§ 387 Records to be kept by State Commissioner of Health The State Commissioner of Health shall prepare, print, and supply to all registrars all blanks and forms used in registering, recording and preserving the returns, or in otherwise carrying out the purposes of this article, and shall prepare and issue such detailed instructions, not inconsistent with the regulations established by the public health council, as may be required to procure the uniform observance of its provisions and the maintenance of a perfect system of registration, and no other blanks shall be used than those supplied by the State Commissioner of Health He shall carefully examine the certificates received monthly from the registrars, and if any such are incomplete or unsatisfactory he shall require such further information to be supplied as may be necessary to make the record complete and satisfactory All physicians, midwives, undertakers, or informants, and all other persons having knowledge of the facts, are hereby required to supply, upon a form provided by the State Commissioner of Health or upon the original certificate, such information as they may possess regarding any birth or death upon demand of the State Commissioner of Health, in person, by mail, or through the registrar, provided, that no certificate of birth or death, after its acceptance for registration by the registrar,

and no other record made in pursuance of this article, shall be altered or changed in any respect otherwise than by amendments properly dated, signed and witnessed The State Commissioner of Health shall arrange, and permanently preserve the certificates in a systematic manner, and shall prepare and maintain a comprehensive and continuous typewritten or printed index of all births and deaths registered, said index to be arranged alphabetically, in case of deaths, by the names of decedents, and in the case of births, by the names of fathers or mothers if born out of wedlock. He shall inform all registrars what diseases are to be considered infectious, contagious, or communicable and dangerous to the public health, as decided by the public health council [in order that] *and* when deaths occur from such diseases *the registrar shall forthwith report to the local health officer, on a form provided for the purpose, the name, age, and address of the deceased, together with the disease, and the name of the physician who has certified the cause of death, so that proper precautions may be taken to prevent their spread*

§ 6 Section three hundred and eighty-nine of such chapter, as added by chapter six hundred and nineteen of the laws of nineteen hundred and thirteen, and last amended by chapter one hundred and sixty-eight of the laws of nineteen hundred and twenty-four, is hereby amended to read as follows

§ 389 District records to be kept by registrar Each registrar shall supply blank forms of certificates to such persons as require them Each registrar shall carefully examine each certificate of birth or death when presented for record in order to ascertain whether or not it has been made out in accordance with the provisions of this act and the instructions of the State Commissioner of Health, and if any certificate of death is incomplete or unsatisfactory, it shall be his duty to call attention to the defects in the return, and he may withhold the burial or removal permit until such defects are corrected All certificates, either of birth or death, shall be written legibly, in durable black ink, and no certificate shall be held to be complete and correct that does not supply all of the items of information called for therein, or satisfactorily account for their omission If the certificate of death is properly executed and complete, he shall then issue a burial or removal permit to the undertaker, provided, that in case the death occurred from some disease which is held by the public health council to be infectious, contagious, or communicable and dangerous to the public health, no permit for the removal or other disposition of the body shall be issued by the registrar, except to an undertaker licensed under section two hundred and ninety-five of the public health law, under such conditions as may be prescribed by the state public health council If a certificate of birth is incomplete, the local regis-

Penal Law, by permitting use of instruments for contraceptive treatment of married persons

February 27, 1925

#### AN ACT\*

Introduced in the Assembly by Mr Lattin

To amend the public health law, in relation to vital statistics

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Section three hundred and seventy-two of chapter forty-nine of the laws of nineteen hundred and nine, entitled "An act in relation to the public health, constituting chapter forty-five of the consolidated laws," as added by chapter six hundred and nineteen of the laws of nineteen hundred and thirteen, and last amended by chapter two hundred and thirteen of the laws of nineteen hundred and nineteen, is hereby amended to read as follows

§ 372 Registration districts The State shall be divided into registration districts as follows Each city, each incorporated village, and each town, [and each state hospital, charitable or penal institution] shall constitute a primary registration district, provided that the State Commissioner of Health may combine two or more primary registration districts or divide one registration district into two or more primary districts to facilitate registration [,] and he may establish any state hospital, charitable, or penal institution as a primary district When a district is divided into two or more primary registration districts, the appointment of a registrar for each shall be made by the same appointed authority which had jurisdiction over the original district, excepting in the instance of a state hospital, charitable, or penal institution, the registrar for which shall be the superintendent or person in charge as provided in section three hundred and seventy-three

of this chapter When two or more primary districts are combined, the registrar for such combined district shall be appointed at a joint session of the authorities which heretofore made the appointment of registrars of the original districts

Remuneration and expenses of registrars of of districts which have been divided into two or more primary registration districts shall be paid by the municipality comprising the original district, except that the registrar of a state hospital, charitable, or penal institution shall receive no additional remuneration for acting as registrar

Remuneration and expenses of registrars of combined districts shall be paid by the municipalities comprising such districts in proportion as each would be required to compensate a separate registrar for its own district, except that when such combined districts coincide with a consolidated health district the remuneration and expenses of the registrar shall be paid by the consolidated health board of such district as provided by section twenty of chapter three of the public health law

§ 2 Section three hundred and seventy-six of such chapter, as added by chapter six hundred and nineteen of the laws of nineteen hundred and thirteen, is hereby amended to read as follows

§ 376 Registration of stillborn children A stillborn child shall be registered as a birth and also as a death, and separate certificates of both the birth and the death shall be filed with the registrar of vital statistics in the usual form and manner, the certificate of birth to contain in place of the name of the child, the word "still-born", provided, that a certificate of birth and a certificate of death shall not be required for a child that has not advanced to the fifth month of uterogestation *The State Commissioner of Health may furnish a combined birth and death certificate for the recording of stillbirths and may require it to be used instead of the separate birth and death certificates* The medical certificate of the cause of death shall be signed by the attending physician, if any, and shall state the cause of death as "stillborn," with the cause of the stillbirth, if known, whether a premature birth, and, if born prematurely, the period of uterogestation, in months, if known, and a burial or removal permit of the prescribed form shall be required Midwives shall not sign certificates of death for stillborn children, but such cases, and stillbirths occurring without attendance of either physician or midwife shall be treated as death without medical attendance, as hereinafter provided in this article

§ 3 Subdivision twenty-one of section three hundred and eighty-three of such chapter, as added by chapter six hundred and nineteen of the laws of nineteen hundred and thirteen, is hereby amended to read as follows

21 Number of children of this mother [living] born alive, stillborn, and total now living

\* Matter in italics is new matter in brackets [ ] is old law to be omitted

may, upon request, supply to any applicant a certified copy of the record of any birth or death registered under the provisions of this act, for the making and certification of which he shall be entitled to a fee of one dollar, to be paid by the applicant, provided that the United States census bureau may obtain, without expense to the state, transcripts of certified copies of births and deaths without payment of fee here prescribed, for use solely as statistical data. Any copy of the record of a birth or death, when properly certified by the state commissioner of health or person authorized to act for him shall be prima facie evidence in all courts and places of the facts therein stated. For any search of the files and records when no certified copy is made, the state commissioner of health shall be entitled to a fee of fifty cents for each hour or fractional part of an hour of time of search, said fee to be paid by the applicant.

If at any time after the birth, or within one year of the death of any person within the state, a certified copy of the official record of said birth or death with the information required to be registered by this act, be necessary for legal, judicial, or other proper purposes and, after search by the state commissioner of health or his representative, it should appear that no such certificate of birth or death was made and filed as provided by this act, then the [person asking for such certified copy may file a sworn statement, to be accompanied by the affidavits of two competent witnesses, as to the fact of birth or death, with as many particulars of the standard certificate supplied as possible, and the state commissioner of health shall file it and issue a certified copy thereof to said applicant without fee and without charge for time of search, and the] state commissioner of health shall immediately require the physician, or midwife, who, being in attendance upon a birth since the date of the taking effect of this act, failed or neglected to

file a certificate thereof or the undertaker, or other person who having charge of the interment or removal of the body of the deceased person since the date of the taking effect of this act, failed or neglect to file the certificate of death, if he or she be living to obtain and file at once with the local registrar such certificate in as complete form as the lapse of time will permit, together with a fee of five dollars, which shall be transmitted to the state commissioner of health and accounted for as a fee for certified copies. With said certificate shall be filed [the] such sworn statements [and] or affidavits [hereinafter mentioned] as may be required by the state commissioner of health. The delinquent physician, midwife, undertaker, or other person may also, in the discretion of the state commissioner of health be prosecuted as required by this article, and shall be prosecuted without bar from the statute of limitations, if he or she shall neglect or fail to file promptly the certificate required by this section [as a substitute for the certificate not filed as required by this article,] and to pay the filing fee provided for in this section.

*If the physician, midwife, or undertaker responsible for the report, is deceased or cannot be located, then the person making application for the certified copy of the record may file such certificate of birth or death together with such sworn statements and affidavits as the state commissioner of health may require, and the state commissioner of health shall file it and issue a certified copy thereof to said applicant without fee and without charge for time of search.*

The state commissioner of health shall keep a true and correct account of all fees by him received under this section, and turn the same over to the state treasurer.

§ 9 This act shall take effect immediately.

No comment, printed for the information of the profession.

trar shall immediately notify the informant, and require him to supply the missing items of information if they can be obtained. He shall number consecutively the certificates of birth and death, in two separate series, beginning with number one for the first birth and the first death in each calendar year, and sign his name as registrar in attest of the date of filing in his office. He shall also make a complete and [accurate] *accurate* copy of each birth and each death certificate registered by him in a record book supplied by the State Commissioner of Health, to be preserved permanently in his office as the local record, in such manner as directed by the State Commissioner of Health. Within ten days after receiving the certificate of any legitimate birth he shall furnish to the parents or guardian of the child a certificate of registration, to be made out on a form which shall be furnished by the State Commissioner of Health, [except that the issuance of such certificate of registration may be postponed until the child's given name is also registered,] and such certificate of registration shall be accepted by public authorities in this state for the purposes indicated in section three hundred and eighty-eight of this chapter in the same manner as certified copies of birth certificates, he shall also make a notation on his copy of the original birth certificate indicating the date of issuance of such certificate of registration. He shall, on the fifth day of each month transmit to the State Commissioner of Health all original certificates registered by him for the preceding month [ ] *and also any delayed certificates registered by him during the month.* If no births or no deaths occurred in any month, he shall on the fifth day of the following month, report that fact to the State Commissioner of Health on a card provided for such purpose.

*A local registrar may charge a fee of twenty-five cents for a search or fifty cents for a verified transcript of any record of a birth or death recorded in his district, provided, however, that no fee shall be charged for certifications or transcripts to be used for school entrance, employment certificates, or for purposes of government compensation.*

Each registrar shall transmit weekly to the district health officer, if such registrar's primary district is included as part of a general health district established under section twenty-b of article three of this act, on a form or forms to be designed and furnished by the state commissioner of health, a report of the number of births, stillbirths, deaths under one year of age, and total deaths from all causes, and the number of deaths from each disease declared reportable in the state sanitary code, which have been registered in such primary registration district. Such weekly report shall be transmitted to the district health officer on each Saturday morning for the births, stillbirths, and deaths which have been registered during the seven preceding days,

and if no births or deaths have been registered he shall report to this effect. Each registrar shall be paid by the board of health of the general health district twenty cents for each complete weekly report promptly transmitted, for each district which such registrar serves, and such compensation shall be paid annually upon certification by the district health officer to the board of health.

§ 7 Section three hundred and ninety of such chapter as added by chapter six hundred and nineteen of the laws of nineteen hundred and thirteen and last amended by chapter two hundred and thirteen of the laws of nineteen hundred and nineteen, is hereby amended to read as follows:

§ 390 Fees of registrar for the prompt and correct return and filing of birth and death certificates, except as hereinbefore otherwise provided each registrar and each physician and each midwife shall be paid the sum of twenty-five cents for each birth certificate properly and completely made out and registered and each death certificate properly and completely made out in accordance with the international list of causes of death and returned and filed with the registrar and correctly recorded and promptly returned by him to the state commissioner of health, as required by this article. And in case no births or no deaths were registered during any month, the local registrar shall report to that effect. Each local registrar shall be paid the sum of two dollars for a *complete* monthly report to be transmitted on the fifth day of the following month to the state commissioner of health on such form as may be provided or required by the commissioner. All amounts payable to the local registrar under the provisions of this article shall be paid by the municipality comprising the registration district, upon certification by the state commissioner of health and all amounts payable to physicians and midwives shall be certified to by the local registrar annually and paid to said physicians and midwives by said municipality. The state commissioner of health shall annually certify to the municipality the number of births and deaths properly registered, *and of complete monthly reports promptly transmitted*, with the name of the local registrar and the amount due him at the rate fixed herein. In addition thereto the local registrar shall be paid a fee of twenty-five cents for each burial, removal or transit permit issued by him.

§ 8 Section three hundred and ninety-one of such chapter, as added by chapter six hundred and nineteen of the laws of nineteen hundred and thirteen and amended by chapter three hundred and ninety-eight of the laws of nineteen hundred and twenty-one, is hereby amended to read as follows:

§ 391 Certified copies of records, state commissioner of health to furnish. The state commissioner of health or person authorized by him

An outstanding feature of this Memorial is that it is to be directed by medical men rather than laymen, the Governing Committee memberships being composed 75 per cent of scientific medical men and 25 per cent of laity

There are two distinct phases of the Gorgas Memorial

#### 1 Research in tropical diseases

The Panama Government in recognition of the splendid work of William Crawford Gorgas in eliminating yellow fever and controlling malaria, thus making possible the Panama Canal, has donated the site and guaranteed a building (estimated at \$750,000) for tropical research. This Institute will be established in the city of

Panama on the Western coast of the Isthmus and the property will adjoin that of the Santa Tomas Hospital, a \$2,000,000 government hospital, which will be available for men and materials

A portion of the income derived from the Endowment Fund will be utilized in carrying on a national health educational campaign which has for its object the development of a close co-operation between the public and the scientific medical profession

A general knowledge of scientific medicine's achievements will secure the recognition of the scientific doctor as the real medical authority in contradistinction to the irregular cultist whose harmful influence is felt in every community

# State Department of Health

## SYPHILIS NOW ACKNOWLEDGED AS ONE OF THE CHIEF CAUSES OF DEATH

Syphilis is the second principal cause of the cardio-vascular diseases, which are now by far the leading causes of death in the United States. Lamb estimated cardiac involvement to be present in 50-75 per cent of all syphilitics.

For generations there has been a reluctance to mention syphilis publicly or openly to give it as the direct cause of various lesions, estimated to constitute as high as one-third of all pathology, or to sign a death certificate giving syphilis as the cause of death. Public health activities to control venereal infections, inaugurated of neces-

sity during the World War, have been instrumental in bringing this "Great Imitator" and the most interesting of diseases, into the open as an infectious, and not necessarily a moral, condition.

Reid, in the *American Journal of Syphilis* for October, 1924, emphasizes that once infection has taken place efforts should be directed to prevent serious cardiac and aortic injuries, and that the disease calls for the careful attention of the whole profession and not merely that of specialists.

## TWO BROTHERS DIE FROM DIPHTHERIA ON THE SAME DAY

The Department has recently received a report on the deaths from diphtheria on the same day of two brothers in one of the cities in the north-western part of the State. According to this history, one of the patients, seven years of age, had symptoms four days before death and three days before a physician was called. In this case the primary site of the disease was in the nose, the larynx being subsequently involved. The physician who saw the patient on the third day of the disease did not make a diagnosis of diphtheria. Another physician was called on the fourth day,

and gave 10,000 units of antitoxin. The report indicates that the parents refused to have antitoxin given the other child, two years of age. The mode of death in both cases, as stated in the report, was respiratory obstruction.

The tragedy in this family adds another to a long list of instances where parents have neglected to call physicians sufficiently early, and the not inconsiderable list of cases in which a more careful examination by the attending physician might have resulted in an earlier diagnosis, with possible saving of life.

## PHYSICIAN FAILS TO TAKE CULTURE OR GIVE ANTITOXIN CHILD DIES

In a second class city in central New York a physician was called to see a case of sore throat on February 3. A greenish gray membrane was present in the throat. According to information received by the Department this physician continued to treat the case during the rest of the week, and although later admitting a knowledge of the desperate condition of the child, did not take a culture or give antitoxin "as the health officer would say it was diphtheria and put a sign on the house." No antitoxin was given "as it weakens the heart and they die when you give

it." The family was told to remain in the house and to allow no visitors. Five days after the child was first seen this doctor advised that a nose and throat specialist be called. The latter immediately made a clinical diagnosis of diphtheria, gave 60,000 units of antitoxin and took a culture which later was reported positive, but the administration of antitoxin had been delayed too long. Despite the efforts of the specialist the child died twelve hours later. Two other children in the family are reported as ill and in both cases positive cultures have been obtained.

## EFFECTIVENESS OF HEALTH TALKS

It is often difficult for people not directly interested in promoting health activities to appreciate the eagerness of the public for accurate and scientific information on health questions. The desire on the part of the masses for authoritative data on the prevention of venereal diseases is shown by the large number of requests for literature that follow each lecture. It is probably due

to the fact that the subject of gonorrhea and syphilis has been taboo for so many years. The public now recognizes these as communicable diseases and understands that their treatment and prevention require controlling measures similar to those that have proved efficacious in the reduction of other contagious diseases.

hand we are not sure of a positive diagnosis with an abnormal "sugar curve" Nephritis, arteriosclerosis, lues, carcinoma, hyperthyroidism, advancing years and other conditions apparently bring about pictures resembling those characteristic of diabetes. The greatest caution is therefore necessary in interpreting them

#### SUMMARY

1 Overindulgence in food and a sedentary mode of life favor the development of "latent diabetes"

2 Hereditary cases of diabetes have been recorded, the children of diabetic parents should be watched carefully

3 The earlier treatment is begun the better is the chance of keeping the disease in check and not having it become severe so as to threaten life in itself or by its complications

4 The best means of early diagnosis is urine analysis, frequently repeated, blood sugar determinations as a diagnostic aid must be interpreted very cautiously

### KINGS COUNTY AGAINST THE MEDICAL PRACTICE ACT OF 1925

Along somewhere in the early part of December, 1924, the newly elected President of the Medical Society of the County of Kings, Dr John E. Jennings, said to the writer "With reference to legislative changes in the Medical Practice Act, especially the re-registration feature, I don't think Kings ought to be satisfied with simply the decision of any one meeting no matter how well or poorly attended. In my opinion we ought to get out a questionnaire to all the physicians in Brooklyn, so I would like you to pick a committee of four others and draw it up"

Promptly I appointed a committee consisting of two strong advocates of annual registration (one a former President of the State Society) and two bitter opponents of registration, annual or any other kind. The proponents of registration opposed a questionnaire claiming "A referendum would be most unfortunate, as a relatively small percentage of the voters will be familiar with the bill." Finally we all agreed to fall back on the January 20th meeting making an extra effort to get a large crowd out.

The night of the meeting was the worst storm of the winter. The attendance was 155. Dr Downing and Dr Rypins of the State Education Department had the floor for over two hours pleading the cause of the Karle-Dunmore 1925 Medical Practice act with its registration features. This was followed by open and very free discussion from the floor led by Dr John O'Reilly, Dr Richard Kevin and Dr Charles Gordon, in the course of which Dr Downing admitted that last year in the closing days of the legislative session the chiropractors had succeeded in amending in the Assembly the Lattin portion of the Carroll-Lattin bill excluding them from the provisions of the act and this had been consented to by the Attorney-General and the State Department of Education. Promptly the Society voted its opposition to the Karle-Dunmore Bill and referred it to the legislative committee. If this committee voted unanimously one way or another, that is for or against the bill, the Society was to stand behind it, whereas if the committee

was split, there was to be a majority and minority report and the whole registration problem would be submitted by mail to the 1,600 members in the Society.

Ten days later the committee met and went carefully over the new matter in the bill, line for line with Judge John Dyer, counsel for the County Society. After long deliberation and free discussion the committee cast one vote in unanimous opposition to the bill.

On February 17th the findings of the committee were reported to the Society at the regular monthly meeting and the report was unanimously adopted by the Society with instructions to send a copy of the same to every County Legislative Chairman, and every County Society in the State, seeking comment and advice.

Thus far I have given a brief outline of how Kings County tries to swing the "Mother Society" by giving over its platform continually and continuously to the advocates of changing the Medical Practice Act and incorporating the—to us—unpleasant features of annual registration, etc but always with the same result. Does the reader know that out of the last nine meetings of our Society covering a period of fourteen months four meetings in their entirety have been given over to one legislative feature only—the Medical Practice act (1924 then 1925)?

In January, 1924, Dr Vander Veer and Dr Rypins appeared before us with a bill which the Society rejected and for which Counsellor Whiteside of the State Society complimented us saying the bill was vicious.

In February, 1924, Dr Wightman and Counsellor Whiteside appeared before us with the Carroll-Lattin bill which we rejected. Later on we asked the Chairman of the Senate Health Committee to take the bill out of committee, and we did this for the sake of unanimity with the State Society. Then we heard about the atrocious amendment excluding chiropractors and we got busy with our own Assemblymen, and we are glad to say every Assemblymen in Kings and Queens Counties (33) voted to re-commut

# NEWS NOTES

## DIABETES MELLITUS IN PERIODIC HEALTH EXAMINATIONS

By HERMAN O MOSENTHAL, M.D.,

NEW YORK CITY

Abstract of the fourteenth lecture in the Symposium on Health Examinations conducted by the Medical Society of the County of New York, given January 27, 1925

During the past forty years the incidence of diabetes mellitus has increased enormously, in the registration area of the United States the death rate per 100,000 of population from diabetes has risen from 28 to 161, while the death rate from all causes diminished during this period. Diabetes in the United States now stands twelfth in numerical order as a cause of death.

The significance of this rise in the diabetic mortality rate is not generally appreciated. The usual explanation given is that our methods of diagnosis and the thoroughness of physical examination have changed for the better to such a degree that our diagnoses have become more accurate. This may be true of the early and mild cases, but surely does not apply to the severely ill and moribund. A simple routine urine analysis reveals the situation now as it did forty years ago. The cause for increased diabetic mortality must be sought in other directions.

Experiences during the world war gave us a very distinct indication that a low caloric diet reduced the incidence of diabetes to a considerable extent, not only that, but the lives of diabetics were prolonged under these circumstances. In France, England and the United States there has been a direct ratio between diabetes on the one hand and the number of calories consumed per capita on the other. In other words, as the dietary habits of a country have become more luxurious, the occupations more sedentary, the nation more prosperous, diabetes has become more prevalent. This in all probability is due to the fact that if a diminished ability to utilize carbohydrates—a "prediabetic condition"—exists in an individual, it is brought to the fore by overeating and underexercising, it is not likely that such habits induce diabetes in anyone not predisposed to it. However, the data we have are a very striking demonstration of the number of potential diabetics among us, they also show that living sensibly and moderately puts less strain upon our carbohydrate digesting functions than over-indulgence in food and an absolutely sedentary life.

*Heredity*—In some families diabetes is a distinctly "hereditary disease." Van Noorden and others have published very interesting examples of this kind. It may be that this idea has been

somewhat exaggerated since it is not to be wondered at, considering the prevalence of diabetes, that about 20 per cent of these sufferers should have an instance of diabetes existing among their forebears. However we may regard this matter, it is a wise precaution to have frequent urine analyses in children of diabetic parents and thus enable us to detect the disease at the earliest possible moment and treat it to the greatest advantage.

*Nervous Strain* will often aggravate an existing diabetes. It is doubtful whether nervous strain or shock in itself can initiate diabetes, the lessened incidence of the disease during the war would bear out this statement.

*The Importance of Early Diagnosis*—In most diabetics the over-strain of sugar-utilizing functions, as evidenced clinically by glycosuria, is followed by a further impairment of carbohydrate digestion. Hence an early diagnosis and prompt treatment may prevent the condition from becoming severe and keep it within the category of mild ailments rather than a life-threatening scourge.

*The Means of Early Diagnosis*—Urine analyses today are easily obtained and if frequently repeated constitute the surest guide to the early detection of diabetes. Such monthly urine examinations, preferably of the afternoon or evening specimens, should be carried out in all suspected cases. No routine physical examination should be considered complete without a urinary test. In my experience the analysis of urine by the patient or prospective patient is to be avoided, such amateur chemists, as well as their immediate families, often become professional neurotics.

A single blood sugar determination taken two hours after breakfast or later in the day may furnish confirmatory evidence of the urinary findings.

The final appeal in diagnosis of diabetes has been and still is the sugar tolerance tests. About 100 grams of glucose are given to the fasting patient. If during two hours the blood sugar returns to the fasting level and at no time during this period rises above 150 mgm. per 100 c.c. we are not dealing with a diabetic. On the other

hand we are not sure of a positive diagnosis with an abnormal "sugar curve" Nephritis, arteriosclerosis, lues, carcinoma, hyperthyroidism, advancing years and other conditions apparently bring about pictures resembling those characteristic of diabetes. The greatest caution is therefore necessary in interpreting them

#### SUMMARY

1 Overindulgence in food and a sedentary mode of life favor the development of "latent diabetes"

2 Hereditary cases of diabetes have been recorded, the children of diabetic parents should be watched carefully

3 The earlier treatment is begun the better is the chance of keeping the disease in check and not having it become severe so as to threaten life in itself or by its complications

4 The best means of early diagnosis is urine analysis, frequently repeated, blood sugar determinations as a diagnostic aid must be interpreted very cautiously

### KINGS COUNTY AGAINST THE MEDICAL PRACTICE ACT OF 1925

Along somewhere in the early part of December, 1924, the newly elected President of the Medical Society of the County of Kings, Dr John E. Jennings, said to the writer "With reference to legislative changes in the Medical Practice Act, especially the re-registration feature, I don't think Kings ought to be satisfied with simply the decision of any one meeting no matter how well or poorly attended. In my opinion we ought to get out a questionnaire to all the physicians in Brooklyn, so I would like you to pick a committee of four others and draw it up"

Promptly I appointed a committee consisting of two strong advocates of annual registration (one a former President of the State Society) and two bitter opponents of registration, annual or any other kind. The proponents of registration opposed a questionnaire claiming "A referendum would be most unfortunate, as a relatively small percentage of the voters will be familiar with the bill". Finally we all agreed to fall back on the January 20th meeting making an extra effort to get a large crowd out

The night of the meeting was the worst storm of the winter. The attendance was 155. Dr Downing and Dr Rypins of the State Education Department had the floor for over two hours pleading the cause of the Karle-Dunmore 1925 Medical Practice act with its registration features. This was followed by open and very free discussion from the floor led by Dr John O'Reilly, Dr Richard Kevin and Dr Charles Gordon, in the course of which Dr Downing admitted that last year in the closing days of the legislative session the chiropractors had succeeded in amending in the Assembly the Lattin portion of the Carroll-Lattin bill excluding them from the provisions of the act and this had been consented to by the Attorney-General and the State Department of Education. Promptly the Society voted its opposition to the Karle-Dunmore Bill and referred it to the legislative committee. If this committee voted unanimously one way or another, that is for or against the bill, the Society was to stand behind it, whereas if the committee

was split, there was to be a majority and minority report and the whole registration problem would be submitted by mail to the 1,600 members in the Society

Ten days later the committee met and went carefully over the new matter in the bill, line for line, with Judge John Dyer, counsel for the County Society. After long deliberation and free discussion the committee cast one vote in unanimous opposition to the bill.

On February 17th the findings of the committee were reported to the Society at the regular monthly meeting and the report was unanimously adopted by the Society with instructions to send a copy of the same to every County Legislative Chairman, and every County Society in the State, seeking comment and advice.

Thus far I have given a brief outline of how Kings County tries to swing the "Mother Society" by giving over its platform continually and continuously to the advocates of changing the Medical Practice Act and incorporating the—to us—unpleasant features of annual registration, etc., but always with the same result. Does the reader know that out of the last nine meetings of our Society covering a period of fourteen months four meetings in their entirety have been given over to one legislative feature only—the Medical Practice act (1924 then 1925)?

In January, 1924, Dr Vander Veer and Dr Rypins appeared before us with a bill which the Society rejected and for which Counsellor Whiteside of the State Society complimented us saying the bill was vicious.

In February, 1924, Dr. Wightman and Counsellor Whiteside appeared before us with the Carroll-Lattin bill which we rejected. Later on we asked the Chairman of the Senate Health Committee to take the bill out of committee and we did this for the sake of unanimity with the State Society. Then we heard about the atrocious amendment excluding chiropractors and we got busy with our own Assemblymen, and we are glad to say every Assemblymen in Kings and Queens Counties (33) voted to re-committ

the bill thereby killing it. We then received a tirade of intolerant abuse from all over the State, but we still think we were right.

Now we come to the Karle-Dunmore bill. The findings of the legislative committee which were unanimously adopted by the Society are printed on page 349 in last week's issue of this Journal, but perhaps some of the points in opposition to the bill need further explanation.

One of the reasons we are told why we should be registered is that nine other professions in this State are registered while doctors and lawyers are not. On investigation we find four professions, dentistry, optometry, podiatry and nursing registered, and in each case licenses are subject to revocation or suspension at the discretion of the Regents for failure of the name to appear on the register. We have always claimed that once we are registered, in a short while the law will be amended as some of the other four were to make the security of a license subordinate to registration. We have a vested right in our State license and no degree of discretionary power under re-registration should be allowed to jeopardize it. Not only that but any one can see that compulsory health insurance would be made easy with compulsory registration a law. Furthermore the honest doctor will be registered and must make an affidavit and pay a fee, but the cults—no.

Still again this registration is supposed to be the one and only way of getting at the cults, yet as I pointed out before, the Lattin bill of last year was amended to exclude chiropractors from its provisions. Who is there to assure me that *this* bill will not be amended at the last moment? Kings County was the child that burned its fingers and we are not going to touch the hot stove again. It is the personal belief of the writer that the chiropractors, very much enheartened by getting in their amendment last year, have purposely introduced the Esmond bill which is the Karle-Dunmore bill with Sections added to it, which is the chiropractic bill, in the confident expectation that at the last minute it will be jammed through giving the State Department of Education its registration of physicians provided the chiropractors are licensed. Certainly they are willing to register annually, pay fees, make affidavits, restore Section 170-d having to do with contraceptive measures in their part of the bill, etc., etc., so long as they are licensed, but what will the price of registration be for us?

Another reason why we should be for this bill is because of the fines imposed which would drive out of the State the illegal practitioners, the cultists, etc. We have legal advice that the fines and penalties imposed are so very severe, cruel, and inhuman it is a question if they would be sustained. It was my privilege to appear before Governor Miller at a hearing on a bill

enforcing the Medical Practice act some three or four years ago, and the penalties were so severe he just threw it out. Again Dr Stanton of Schenectady pointed out some time ago in a little pamphlet he issued, that attempts to enforce laws of this type simply makes martyrs of any prosecuted cult and the reaction of the public to martyrs is only too well known. Then again what will happen to such fines as are collected under this new law? They will be used along with the \$2 fee collected from each of us to administer the new law paying the cost of the head of the new department with the salaries of two or three inspectors for the entire State and whatever office force is necessary, also for a special attorney general. At the end of five years we do not pay any further fee but as the State will have been cleaned up and no more fines can be collected it is the impression of many in Kings County that our fee by amending the law will be increased. In one State, I think it is Virginia, the fee is now \$25. Finally if any money is left over at the end of the year, it is turned over to the State Treasurer. Thus we protect the public health and pay for the privilege of so doing. Not even all of our small \$2 is likely to be used for our benefit as whatever portion of it may be turned over to the State Treasurer is used for some other purpose. The County Society under this bill is "OUT FOR GOOD." Under the present law if a county society prosecutes and is successful, it shares in the profits of the fines imposed. Within the last twelve months in Kings County there has been collected in fines \$500 from illegal practitioners of medicine and \$1,300 from chiropractors. Unfortunately we have not got the protecting reserve fund of five or six thousand dollars needed to be the actual plaintiff and so share in the fines. Our District Attorney is the plaintiff and prosecutor on information furnished by the "Illegal Practitioners Committee."

Section 170c has been taken out of the new bill, but later it is put in again. This section related to abortions. Section 170d has been taken out and put back. This has to do with the use of contraceptive measures. Just as we had supposed, there has been introduced already a birth-control bill permitting the use of contraceptive measures in married persons which will go hand in hand with the removal of Section 170d. Why is it taken out? Our counsel tells us that leaving the section out removes one of the grounds for revocation of license. Why? Why not leave it in if there was no real reason for taking it out?

At the present time lists of practicing physicians are available at the County Clerks offices, from the State Medical Society, from the Board of Regents, and several other sources. In fact Dr Downing tells us that the Department of Education recently checked up a list of 10,000

doctors from the Internal Revenue Department. Nevertheless this new bill will supply each physician with a printed list yearly of the licensed men in his State, and he is then requested to report to qualified authorities the names and addresses of any person known to be practicing medicine whose name does not appear in this registry. In other words, there is to be no initiative by the new board created by this bill. All action is to come from practitioners first, so that after protecting the public health and paying for the privilege we are now to do the detective work or the whole thing may not function!

In conclusion it is the general opinion in Kings

County that this bill gives the public health nothing, not even protection. In Connecticut where they have had registration for years, we were treated to a diploma-mill scandal. It gives the medical profession nothing, and all that it might do is covered by existing law, which is not enforced except in Kings County. Try as hard as we have to look at this bill from every angle, we still believe it is unnecessary, unremedial, and uncalled for.

(Signed) JOSEPH A. DRISCOLL, M.D.  
*Chairman Legislative Committee  
Medical Society, County of Kings*

## BRONX COUNTY MEDICAL SOCIETY

A special meeting of the Bronx County Medical Society, held at Hollywood Gardens, 896 Prospect Avenue, on February 4, 1925, was called to order at 9 P. M., the President, Dr. Jacobs, in the chair.

Dr. Allen K. Krause, associate Professor of Medicine, Johns Hopkins University, and Lecturer Trudeau School of Tuberculosis, spoke on "The Historical Relation of Tuberculosis to General Medicine."

It was moved and carried that a vote of thanks be extended to Dr. Krause.

I. J. LANDSMAN, *Secretary*

A regular meeting of the Bronx County Medical Society, held at Hollywood Gardens February 18, 1925. The meeting was called to order at 9 P. M., the President, Dr. Jacobs, in the chair.

Drs. David Berman, Joseph Bronstein, Samuel M. Clurman, Harry J. Lesnick, Benjamin Segal, Jacob H. Landes, Harry Weaver were elected to membership.

Under new business, Dr. Van Etten moved that the Bronx County Medical Society invite the American Medical Association to hold its 1926 meeting in the City of New York. Motion was seconded and carried.

## SCIENTIFIC SESSION

"Relation of County Societies to the State" Society, Joseph S. Lawrence, M.D., Executive Officer Medical Society of the State of New York.

At the conclusion of Dr. Lawrence's discussion of the relationship of the County Societies to the State Society and summary of the bills affecting the medical profession now before the State Legislature, Dr. Gitlow moved that a set of resolutions be drawn up favoring the proposed Medical Practice Act and that these resolutions be forwarded to the *State Journal*, to Governor Smith and to the Legislature signifying our approval of the act. This motion was seconded by Dr. Cunniffe, was put to vote and carried.

"Human Constitution in Relation to Disease," George Draper, M.D., New York City.

Discussion Drs. Herrman, Lukin, Weiskopf and Zuckerman. Dr. Draper closed the discussion.

Dr. Van Etten moved that a vote of thanks be extended to Dr. Draper for his most interesting paper. Seconded and carried, the President, Dr. Jacobs, extended the thanks of the Society to Dr. Draper.

The meeting adjourned at 11 P. M.

I. J. LANDSMAN, *Secretary*

---

## MEDICAL SOCIETY OF THE COUNTY OF GREENE

The meeting was called to order at 8:45 P. M., at the Saulpaugh Hotel. The President in the chair.

Members present: Drs. Honeyford, Willard, Goodrich, Waller, Daley, A. O. Person, R. E. Person, Van Dusen, Van Slyke, and Rapp. Dr. Huntington Williams, District State Health Officer, was guest of the meeting.

The minutes of the last meeting were read for information only.

Dr. Waller, Chairman of the Committee on Legislation, reported on his activities in relation to bills introduced in the State Legislature, particularly in regard to the chiropractic bill introduced by Senator Bouton. Dr. Waller reported that he had already written Senator Bouton.

Dr. Van Dusen introduced the following resolution:

"Resolved, that we the members of the Medical Society of the County of Greene, are unalterably opposed to the chiropractic bill introduced by

the bill thereby killing it. We then received a tirade of intolerant abuse from all over the State, but we still think we were right.

Now we come to the Karle-Dunmore bill. The findings of the legislative committee which were unanimously adopted by the Society are printed on page 349 in last week's issue of this Journal, but perhaps some of the points in opposition to the bill need further explanation.

One of the reasons we are told why we should be registered is that nine other professions in this State are registered while doctors and lawyers are not. On investigation we find four professions, dentistry, optometry, podiatry and nursing registered, and in each case licenses are subject to revocation or suspension at the discretion of the Regents for failure of the name to appear on the register. We have always claimed that once we are registered, in a short while the law will be amended as some of the other four were to make the security of a license subordinate to registration. We have a vested right in our State license and no degree of discretionary power under re-registration should be allowed to jeopardize it. Not only that but any one can see that compulsory health insurance would be made easy with compulsory registration a law. Furthermore the honest doctor will be registered and must make an affidavit and pay a fee, but the cults—no.

Still again this registration is supposed to be the one and only way of getting at the cults, yet as I pointed out before, the Lattin bill of last year was amended to exclude chiropractors from its provisions. Who is there to assure me that *this* bill will not be amended at the last moment? Kings County was the child that burned its fingers and we are not going to touch the hot stove again. It is the personal belief of the writer that the chiropractors, very much enheartened by getting in their amendment last year, have purposely introduced the Esmond bill which is the Karle-Dunmore bill with Sections added to it, which is the chiropractic bill, in the confident expectation that at the last minute it will be jammed through giving the State Department of Education its registration of physicians provided the chiropractors are licensed. Certainly they are willing to register annually, pay fees, make affidavits, restore Section 170-d having to do with contraceptive measures in their part of the bill, etc., etc., so long as they are licensed, but what will the price of registration be for us?

Another reason why we should be for this bill is because of the fines imposed which would drive out of the State the illegal practitioners, the cultists, etc. We have legal advice that the fines and penalties imposed are so very severe, cruel, and inhuman it is a question if they would be sustained. It was my privilege to appear before Governor Miller at a hearing on a bill

enforcing the Medical Practice act some three or four years ago, and the penalties were so severe he just threw it out. Again Dr Stanton of Schenectady pointed out some time ago in a little pamphlet he issued, that attempts to enforce laws of this type simply makes martyrs of any prosecuted cult and the reaction of the public to martyrs is only too well known. Then again what will happen to such fines as are collected under this new law? They will be used along with the \$2 fee collected from each of us to administer the new law paying the cost of the head of the new department with the salaries of two or three inspectors for the entire State and whatever office force is necessary, also for a special attorney general. At the end of five years we do not pay any further fee but as the State will have been cleaned up and no more fines can be collected it is the impression of many in Kings County that our fee by amending the law will be increased. In one State, I think it is Virginia, the fee is now \$25. Finally if any money is left over at the end of the year, it is turned over to the State Treasurer. Thus we protect the public health and pay for the privilege of so doing. Not even all of our small \$2 is likely to be used for our benefit as whatever portion of it may be turned over to the State Treasurer is used for some other purpose. The County Society under this bill is "OUT FOR GOOD." Under the present law if a county society prosecutes and is successful, it shares in the profits of the fines imposed. Within the last twelve months in Kings County there has been collected in fines \$500 from illegal practitioners of medicine and \$1,300 from chiropractors. Unfortunately we have not got the protecting reserve fund of five or six thousand dollars needed to be the actual plaintiff and so share in the fines. Our District Attorney is the plaintiff and prosecutor on information furnished by the "Illegal Practitioners Committee."

Section 170c has been taken out of the new bill, but later it is put in again. This section related to abortions. Section 170d has been taken out and put back. This has to do with the use of contraceptive measures. Just as we had supposed, there has been introduced already a birth-control bill permitting the use of contraceptive measures in married persons which will go hand in hand with the removal of Section 170d. Why is it taken out? Our counsel tells us that leaving the section out removes one of the grounds for revocation of license. Why? Why not leave it in if there was no real reason for taking it out?

At the present time lists of practicing physicians are available at the County Clerks offices, from the State Medical Society, from the Board of Regents, and several other sources. In fact Dr Downing tells us that the Department of Education recently checked up a list of 10,000

doctors from the Internal Revenue Department. Nevertheless this new bill will supply each physician with a printed list yearly of the licensed men in his State, and he is then requested to report to qualified authorities the names and addresses of any person known to be practicing medicine whose name does not appear in this registry. In other words there is to be no initiative by the new board created by this bill. ## BRONX COUNTY MEDICAL SOCIETY.

A special meeting of the Bronx County Medical Society, held at Hollywood Gardens, 896 Prospect Avenue, on February 4, 1925, was called to order at 9 P. M., the President, Dr. Jacobs in the chair.

Dr. Allen K. Krause, associate Professor of Medicine, Johns Hopkins University and Lecturer Trudeau School of Tuberculosis spoke on "The Historical Relation of Tuberculosis to General Medicine."

It was moved and carried that a vote of thanks be extended to Dr. Krause.

I. J. LANDSMAN, Secretary.

A regular meeting of the Bronx County Medical Society, held at Hollywood Gardens February 18, 1925. The meeting was called to order at 9 P. M., the President Dr. Jacobs in the chair.

Drs. David Berman, Joseph Bronstein, Samuel M. Clurman, Harry J. Lesnick, Benjamin Segal, Jacob H. Landes, Harry Weaver were elected to membership.

Under new business Dr. Van Etten moved that the Bronx County Medical Society invite the American Medical Association to hold its 1926 meeting in the City of New York. Motion was seconded and carried.

## SCIENTIFIC SESSION

Relation of County Societies to the State Society. Joseph S. Lawrence, M.D., Executive Officer Medical Society of the State of New York.

At the conclusion of Dr. Lawrence's discussion of the relationship of the County Societies to the State Society and summary of the bills affecting the medical profession now before the State Legislature, Dr. Gitlow moved that a set of resolutions be drawn up favoring the proposed Medical Practice Act and that these resolutions be forwarded to the *State Journal*, to Governor Smith and to the Legislature signifying our approval of the act. This motion was seconded by Dr. Cunniffe, was put to vote and carried.

Human Constitution in Relation to Disease. George Draper, M.D., New York City.

Discussion. Drs. Herman Lukan, Wenskopf and Zuckerman. Dr. Draper closed the discussion.

Dr. Van Etten moved that a vote of thanks be extended to Dr. Draper for his most interesting paper. Seconded and carried, the President Dr. Jacobs, extended the thanks of the Society to Dr. Draper.

The meeting adjourned at 11 P. M.

I. J. LANDSMAN, Secretary.

## MEDICAL SOCIETY OF THE COUNTY OF GREENE.

The meeting was called to order at 8:45 P. M. at the Saulpaugh Hotel. The President in the chair.

Members present: Drs. Honeyford, Willard, Goodrich, Waller, Daley, A. O. Person, R. E. Person, Van Dusen, Van Slyke, and Rapp. Dr. Huntington Williams, District State Health Officer, was guest of the meeting.

The minutes of the last meeting were read for information only.

Dr. Waller, Chairman of the Committee on Legislation, reported on his activities in relation to bills introduced in the State Legislature, particularly in regard to the chiropractic bill introduced by Senator Bouton. Dr. Waller reported that he had already written Senator Bouton.

Dr. Van Dusen introduced the following resolution:

'Resolved that we the members of the Medical Society of the County of Greene, are unalterably opposed to the chiropractic bill introduced by

Senator Bouton, also to any bill to license any one to practice medicine in the State of New York unless he or they have complied with the same educational requirements we have had to, and that a copy of this resolution be sent to Senator Bouton and to Dr Joseph Lawrence for his use at the hearing in Albany"

On motion duly made and seconded the above resolution was adopted as read

Dr Van Dusen made a motion that a copy of the above resolution be sent to the Ulster County Medical Society and to Assemblyman Bentley It was seconded by Dr Rapp and carried

Dr Van Dusen also moved that the president appoint a committee to wait upon the Chairman of the Republican County Committee in regard to this matter, it was seconded by Dr A O Person and carried The President appointed Drs Van Dusen, Rapp and R E Person as such committee

Under the head of unfinished business the Committee appointed to interview the Board of Supervisors relative to the employment of two nurses for the county made their report.

Dr Waller made a motion that the President appoint a committee to draft resolutions on the death of Drs Griffin, Conklin and Jennings, and that they be spread on the minutes and copy sent to the widows It was seconded by Dr Goodrich and carried

The President appointed Drs Rapp, Willard and R E Person as such committee

Dr Williams addressed the Society on the administration of toxin-antitoxin to school children A general discussion followed, most of the members apparently being in favor of it

Dr Waller moved that the meeting be adjourned to the second Tuesday in May and that it be held at Catskill It was seconded by Dr Willard and carried

---

### TOMPKINS COUNTY MEDICAL SOCIETY

The regular meeting of the Tompkins County Medical Society was held in the Chamber of Commerce parlors, Tuesday evening, February 17th, President John W Judd in the chair

A goodly number of members were in attendance, also a number from the Graduate Nurse's Association and from the City Hospital, invitations having been extended to them for this meeting

The minutes of the January meeting were read and approved as read

Following the business session Dr Frank Howard Richardson of Brooklyn presented a paper on "Practical Breast Feeding" Dr Richardson also has had a large experience in the feeding of infants, believes that they should be breast fed if possible, and thinks that a great many more cases can be so fed than is now done

He stated that the mortality in favor of breast feeding over bottle feeding is in the ratio of 1 to 5 The doctor gave in great detail the latest

methods of accomplishing breast feeding in difficult cases and how to promote and maintain the supply of breast milk, and gave demonstrations on three patients presented

The paper and talk was of intense interest and many questions were asked bringing out additional points and discussion

Dr Bertis R Wakeman of Hornell was present and gave an account of his work which he stated had been gaining adherents ever since it was started among doctors, nurses and mothers

Dr J A Conway of Hornell also spoke in favor of the work

Dr L T Genung moved a vote of thanks to the speakers and offered the following resolution, both of which were adopted

*Resolved*, The Tompkins County Medical Society endorses breast feeding as presented by Dr Richardson and hereby requests our State District Health Officer, Dr Conway, to have a nurse sent to us to teach the method

---

### COUNTY MEDICAL SOCIETY BULLETINS

We are pleased to welcome the appearance of two additional Bulletins of County Medical Societies

The Medical Society of the County of Albany began the publication of a four-page "Bulletin" in January, 1925, and we have received the first two numbers Each contains a notice of the coming monthly meeting, and prints comments on medical matters in which the Society is taking an active part It is emphasizing the work of

the Committee on Periodic Health Examinations, and carries a few personal items

The two issues are a credit to the medical profession of Albany and doubtless will have to be enlarged to keep pace with the activities of the Society

The Medical Society of the County of Queens issued Volume 1, number 1 of its "Bulletin," on February 20, 1925 The Bulletin contains eight pages, one of which carries advertisements It

contains a list of the officers and committees of the Society, and a program of the February meeting. It carries an account of the January meeting and a summary of the papers which were read. It also prints extracts from the Principles of Medical Ethics and comments on local medi-

cal affairs, and lightens its pages with a few lines of humor.

The list of County Societies issuing publications regularly is, New York (weekly), Erie, Bronx, Kings, Queens, Albany and Suffolk.

F O

### MEDICAL SOCIETY OF THE COUNTY OF ONEIDA

The annual meeting of the Medical Society of the County of Oneida was held on January 13th, 1925, in the Hotel Utica. The following officers for 1925 were elected: President, Dr. D. E. Pugh, Vice-President, Dr. J. L. Kelly, Rome, Secretary, Dr. William Hale, Jr., Treasurer, Dr. Hyzer W. Jones, Librarian, Dr. T. Wood Clarke, Censors, Dr. G. M. Fisher, Dr. W. B. Roemer, Dr. G. M. Lewis, Vernon, Dr. H. F. Hubbard, Rome, Dr. R. D. Helmer, Delegates to State Society, Dr. G. M. Fisher, Dr. Robert L. Bartlett, alternates, Dr. D. H. Roberts, Dr. E. R. Evans.

Resolutions on the death of Dr. Roy B. Dudley were adopted.

Dr. Owen E. Jones, Rochester, President of the Medical Society of the State of New York, made an able and thoughtful address on the subject of progress in the medical profession. He showed how it is more and more the practice to have periodical examinations thoroughly made of a person to keep them in health, conserve their strength and prolong their days.

Dr. Joseph S. Lawrence, executive officer of the State Society, spoke along similar lines. He

emphasized the necessity of co-operation, and the importance of periodic examinations of patients. There are 9,000 physicians in this state who are giving yearly \$500,000 in free service to the sick poor. He advised the Society to have clinics on certain subjects, and invite specialists to conduct them. All the meetings of the Society should be instructive.

A resolution to increase the annual dues of the Society from \$2.00 to \$10.00 was discussed at length and was finally rejected by a vote of 17 ayes to 36 noes.

A resolution to meet six times a year instead of four times was adopted by unanimous vote. Future meetings will be held in January, March, May, July, September and November.

The Society discussed the need of a sanatorium for the care of incipient tuberculosis. The Society voted to approve the project and appointed the following committee to promote the plan:

Dr. Florence I. Staunton, Utica, Dr. D. M. Allison, Camden, Dr. Roy J. Marshall, Rome, Dr. Stephen L. Taylor, Kenwood.

### THE ASSOCIATED PHYSICIANS OF LONG ISLAND

The twenty-seventh annual meeting of the Associated Physicians of Long Island was held on Wednesday afternoon and evening, January 28th, at the Maitland Club, Brooklyn. The President, Dr. Herbert Dana Schenck, of Brooklyn, presided, and over one hundred members were present. The meeting was opened at 4:30 o'clock with a business session. Twelve new members were admitted. The Secretary reported that the present enrollment was 985 members.

The Treasurer reported that all expenses of the Association had been met and that a balance of over seven hundred dollars remained. It was voted to make the annual dues five dollars in order to insure adequate funds to conduct the *Long Island Medical Journal* in an efficient manner.

The following officers were elected: President, Dr. A. D. Jaques, Lynbrook, Vice-Presidents, Drs. W. A. Sherwood, Brooklyn, L. Howard

Moss, Richmond Hill, Burdge P. MacLean, Huntington, and W. J. Malcolm, Jericho, Secretary, Dr. J. C. Hancock, Brooklyn, Treasurer, Dr. H. C. Courten, Richmond Hill.

The scientific session was opened at five o'clock at which four papers were presented. Dr. John Joseph Nutt, Professor of Orthopedic Surgery at the University and Bellevue Hospital Medical College, New York, gave a practical talk on lower backache from an etiological and therapeutic standpoint. He dwelt especially on the milder lesions of the sacro-iliac joint, and used a medical student to demonstrate the method of examining the joints and the treatment by strapping the pelvis with a circle of adhesive plaster applied just below the crest of the ileum. The talk was extremely practical and useful, for the condition which he described is common and the proper method of treatment is satisfactory.

Senator Bouton, also to any bill to license any one to practice medicine in the State of New York unless he or they have complied with the same educational requirements we have had to, and that a copy of this resolution be sent to Senator Bouton and to Dr Joseph Lawrence for his use at the hearing in Albany"

On motion duly made and seconded the above resolution was adopted as read

Dr Van Dusen made a motion that a copy of the above resolution be sent to the Ulster County Medical Society and to Assemblyman Bentley It was seconded by Dr Rapp and carried

Dr Van Dusen also moved that the president appoint a committee to wait upon the Chairman of the Republican County Committee in regard to this matter, it was seconded by Dr A O Person and carried The President appointed Drs Van Dusen, Rapp and R E Person as such committee

Under the head of unfinished business the Committee appointed to interview the Board of Supervisors relative to the employment of two nurses for the county made their report.

Dr Waller made a motion that the President appoint a committee to draft resolutions on the death of Drs Griffin, Conklin and Jennings, and that they be spread on the minutes and copy sent to the widows It was seconded by Dr Goodrich and carried

The President appointed Drs Rapp, Willard and R E Person as such committee

Dr Williams addressed the Society on the administration of toxin-antitoxin to school children A general discussion followed, most of the members apparently being in favor of it.

Dr Waller moved that the meeting be adjourned to the second Tuesday in May and that it be held at Catskill It was seconded by Dr Willard and carried

---

### TOMPKINS COUNTY MEDICAL SOCIETY

The regular meeting of the Tompkins County Medical Society was held in the Chamber of Commerce parlors, Tuesday evening, February 17th, President John W Judd in the chair

A goodly number of members were in attendance, also a number from the Graduate Nurse's Association and from the City Hospital, invitations having been extended to them for this meeting

The minutes of the January meeting were read and approved as read

Following the business session Dr Frank Howard Richardson of Brooklyn presented a paper on "Practical Breast Feeding" Dr Richardson also has had a large experience in the feeding of infants, believes that they should be breast fed if possible, and thinks that a great many more cases can be so fed than is now done

He stated that the mortality in favor of breast feeding over bottle feeding is in the ratio of 1 to 5 The doctor gave in great detail the latest

methods of accomplishing breast feeding in difficult cases and how to promote and maintain the supply of breast milk, and gave demonstrations on three patients presented

The paper and talk was of intense interest and many questions were asked bringing out additional points and discussion

Dr Bertis R Wakeman of Hornell was present and gave an account of his work which he stated had been gaining adherents ever since it was started among doctors, nurses and mothers.

Dr J A Conway of Hornell also spoke in favor of the work

Dr L T Genung moved a vote of thanks to the speakers and offered the following resolution, both of which were adopted

*Resolved*, The Tompkins County Medical Society endorses breast feeding as presented by Dr Richardson and hereby requests our State District Health Officer, Dr Conway, to have a nurse sent to us to teach the method

---

### COUNTY MEDICAL SOCIETY BULLETINS

We are pleased to welcome the appearance of two additional Bulletins of County Medical Societies

The Medical Society of the County of Albany began the publication of a four-page "Bulletin" in January, 1925, and we have received the first two numbers Each contains a notice of the coming monthly meeting, and prints comments on medical matters in which the Society is taking an active part It is emphasizing the work of

the Committee on Periodic Health Examinations, and carries a few personal items

The two issues are a credit to the medical profession of Albany and doubtless will have to be enlarged to keep pace with the activities of the Society

The Medical Society of the County of Queens issued Volume 1, number 1 of its "Bulletin," on February 20, 1925 The Bulletin contains eight pages, one of which carries advertisements It

# THE DAILY PRESS

Very few items on the oyster situation now appear in the daily press, but now and then a newspaper follows up the situation with comments on the constructive remedies which have been undertaken in order to insure the healthfulness of the oysters. The *Ithaca Journal News*, February 18th, contains an editorial which will tend to restore public confidence in shellfish. The editorial says

"Coincident with the publication of this report (of the U S Public Health Service) the oyster growers and dealers announce the organization of a vigilance committee to prevent if possible another winter of oyster-bred typhoid with resultant losses which, the oyster men state, have set them back \$30,000,000 during the recent scare.

"This is the kind of news that makes good reading and inspires the public with confidence and intelligence of big business. The first reaction of the oyster boycott on the oyster men was one of natural resentment and denials. Far better the statement issued by William Fellowes Morgan, Jr, president of the Middle Atlantic Oyster Fisheries, saying, 'We have no criticism to make of that action (Health Department restrictions on the sale of oysters). We don't want to make five cents at the expense of public health'."

"While the oyster growers and retailers will not admit that their product was responsible for the typhoid outbreak, they are formulating a code of ethics. This code will stop production of oysters in areas where water pollution is likely, patrol boats which will be floating bacteriological laboratories will be put in service, while dealers are to be educated in the proper method of handling oysters.

"Oysters offer a highly nutritious form of food, especially rich in iodides that keep healthy the important thyroid gland. Their production should be unhindered by public scares. And in this, the cities that empty sewage into coastal waters are more to blame than the oyster men. Perhaps their vigilance committee to be organized with 'real power and responsibility' will look into this situation."

The February 26th issue of the *Brooklyn Eagle* has a column article on the oyster situation from the point of view of the growers of "Blue Points" on the south side of Long Island. It says

"The fog of depression in the oyster industry is lifting here in the home of the world-famous Blue Point. Public confidence in the edible fitness of the oyster is evidenced by the orders coming in and the carload shipments going out

"The Middle Atlantic Fisheries Association, through its vigilance committee, plans to co-operate with the commission appointed at Washington to set up certain standards and regulations to govern all oyster producers in the country. The result would be the establishment of rules and operating conditions that would be above reproach, placing the handling of the shellfish almost on a par with milk production in cleanliness.

"Under the new dispensation the sanitary conditions of the packing and shucking houses, as applying both to the oysters and to the employees handling them, would be of the best. No oyster would be touched by the hand after its final sterilization and packing for shipment. There would be abundant cleansing facilities in the plants and no containers to be refilled that were not of a shape and size easily rinsed out.

## CODE OF ETHICS GOVERN

"The members of the commission appointed in Washington to draw up the new regulations are Surgeon W H Frost and Dr Lewis Radcliffe for the Federal Government, W H Raye and W H Kilian for the Shellfish Dealers and Growers' Association of North America, and Drs H B Costill (New Jersey), J M Fulton (Maryland), Oscar Dowling (Louisiana) and A T McCormick (Kentucky), representing the health departments of their respective States.

"This body will meet in the near future to map out plans to set up standards of handling oysters on the general basis of the eight points agreed to by the conference. The understanding is that the Public Health Service will back up the rules adopted under laws already on the books empowering it to enforce such a 'code of ethics'."

"P O Mercer, head of the big Blue Points Company, has collected these interesting statistics on the scope of the industry: (1) It is located in 19 States, (2) it employs 67,000 persons, (3) the production amounts to 75,000 tons of food ready for the table in normal times, (4) the underwater area involved is more than 1,000,000 acres that would be unadaptable to any other use.

"Oystermen here, while insisting that the local product cultivated and sold by them has not been exposed to any contagious disease, believe firmly that by the time another season rolls around the confidence of the distant consumer will have been fully restored, and that the new order of things will insure an unqualified clean bill of health from the health officials themselves.

"Furthermore, by another year, it is hoped that a process of so clearly identifying the source

Dr Dudley Roberts, of New York, described the serious symptoms produced by the spasm of the union of the esophagus and the stomach and the brilliant results of the simple dilation of the dilating the cardio-spasm under direct fluoroscopic vision

Dr Harold E P Pardee, of New York, read a paper on precordial pain and its relief by removal of the cervical sympathetic ganglia Dr Pardee said that the condition which he described might be called angina pectoris, but the term included a number of different conditions He gave the histories of a number of cases on whom the operation had been done and the object of the operation is to relieve pain, and the results varied from satisfactory to no relief

Dr John E Jennings, of Brooklyn, showed a specimen consisting of about six inches of nerve and ganglia which he had removed from a patient that afternoon

Dr Charles H Peck, of New York, described the surgical aspect of gastric and duodenal ulcer

At seven o'clock the scientific meeting adjourned and the members at once assembled for a dinner in the dining-room In the after-dinner speaking Dr John E Jennings, President of

the Medical Society of the County of Kings, described the educational work of the Society, the Rev John L Davis, of New York, gave an amusing and inspirational address on the Dimensions of Life—its length and breadth, and Judge George W Martin, of Brooklyn, gave some of the merciful principles which actuated him in sentencing prisoners

The Associated Physicians of Long Island is entirely independent of all other medical societies It holds three meetings annually and publishes its own monthly paper, the *Long Island Medical Journal*, which is at the service of the four County Medical Societies on Long Island, and is a great factor in promoting their activities The *Journal* also has a list of over three hundred exchanges in thirty-three foreign countries and is often quoted in the medical journals of those countries because it represents the medical thought of the great City of Brooklyn

The Associated Physicians of Long Island is practically the Second District Branch of the Medical Society of the State of New York Joint meetings of the two organizations have been held in the past, and others are planned for the future  
F O

## DINNER TO CELEBRATE FIFTIETH ANNIVERSARY

A dinner will be tendered to Dr Eliza M Mosher of Brooklyn, on Wednesday evening, March 25, at 7 30 at the new Hotel Roosevelt, Madison Avenue and 45th Street

The dinner is to celebrate the 50th Anniversary of Dr Mosher's entrance into the field of medicine About fifty organizations will be represented Among them are the American Women's Hospitals, Brooklyn Women's Club, Brooklyn Chamber of Commerce, Woman's Club of New York, Women's Medical of the State of New York, Women's Press Club, University of Michigan Alumni of New York, and the University of Michigan

Dr Mosher, who is a graduate in medicine of the University of Michigan, has been connected with Michigan University, as Dean of Women, Professor of Hygiene and Home Economics in the Department of Literature, Science and The Arts, as well as Director of Physical Training for Women She has held the position of Resident Physician and Professor of Physiology in Vassar College, and was a Lecturer at Wellesley and Adelphi Colleges

Recently the Brooklyn Chamber of Commerce appointed Dr Mosher Chairman of a "Cleaner Brooklyn Committee"

Among the speakers at the dinner will be Dr Lewis Stephen Pilcher, presiding, Dr W Seaman Bainbridge, Toastmaster, U S Senator Royal S Copeland, who is a graduate of the University of Michigan, Dr Jos E Raycroft of Princeton University, Dr W Francis Campbell of Brooklyn, Dr John E Jennings, President of the Kings County Medical Society, Dr H Noble MacCracken, President of Vassar College, Mr Arthur Somers, Dr Esther Lovejoy, Miss Jessie Bancroft, and Dr Eliza M Mosher

There will be music and college songs by various groups

Mrs Edward H Cross of 140 W 55th Street, New York City, is the Chairman of the Committee, and the Banquet tickets may be obtained from her The Banquet is limited to 500 tickets and it will be necessary to make early reservations to obtain the most desirable locations

# THE DAILY PRESS

Very few items on the oyster situation now appear in the daily press, but now and then a newspaper follows up the situation with comments on the constructive remedies which have been undertaken in order to insure the healthfulness of the oysters. The *Ithaca Journal News*, February 18th, contains an editorial which will tend to restore public confidence in shellfish. The editorial says:

## CODE OF ETHICS GOVERN

"The members of the commission appointed in Washington to draw up the new regulations are Surgeon W H Frost and Dr Lewis Radcliffe for the Federal Government, W H Raye and W H Kilham for the Shellfish Dealers and Growers' Association of North America, and Drs H B Costill (New Jersey), J M Fulton (Maryland), Oscar Dowling (Louisiana) and A T McCormick (Kentucky), representing the health departments of their respective States.

'This body will meet in the near future to map out plans to set up standards of handling oysters on the general basis of the eight points agreed to by the conference. The understanding is that the Public Health Service will back up the rules adopted under laws already on the books empowering it to enforce such a 'code of ethics'.

"P O Mercer, head of the big Blue Points Company, has collected these interesting statistics on the scope of the industry: (1) It is located in 19 States, (2) it employs 67,000 persons, (3) the production amounts to 75,000 tons of food ready for the table in normal times, (4) the underwater area involved is more than 1,000,000 acres that would be unadaptable to any other use.

"Oystermen here, while insisting that the local product cultivated and sold by them has not been exposed to any contagious disease, believe firmly that by the time another season rolls around the confidence of the distant consumer will have been fully restored, and that the new order of things will insure an unqualified clean bill of health from the health officials themselves.

"Furthermore, by another year, it is hoped that a process of so clearly identifying the source

of shipments will be in force that the practice of substitution among dealers will be wiped out. This has been one of the chief bones of contention among the tongmen in defense of the Great South Bay article. They assert that misleading labels have been used falsely to the discredit of the local product."

---

Troy is now in the midst of a campaign for pure milk. The *Troy Record*, February 17th, contains an editorial comment on a hearing on the milk question before the Common Council, and says

"That public sentiment in this city runs high in regard to the proposed Model Milk Ordinance was definitely proved last night by the tremendous gathering of citizens that attempted first to gain access to the Common Council Chambers in the City Hall and, failing in that, packed the High School auditorium to hear both sides of the argument presented.

"There were two kinds of arguments presented at the hearing last night. The first was the kind that always is heard in such a popular assemblage. Good natured humor and not a little prejudicial oratory was indulged in, and, as is always the case, this expression of sentiment fetched a laugh. Mingled with this was honest conviction that the Milk Ordinance is unnecessary as a health protection. Opposed to these arguments were the hard-and-cold facts offered by men eminent in the medical profession of both the city and the state, proving conclusively that impure milk is one of the contributory causes of Troy's unenviable high infant mortality and conducive to other diseases, and that, being a contributory cause, it should be of a quality that can be safely consumed both by infants and adults. The Council has the facts of the Rensselaer County Medical Society's recent health survey of the county and city, the arguments of other advocates of the ordinances and the endorsements of the ordinance by a large number of civic organizations vitally interested in the health of the city and in a measure designed reasonably to offer a measure of protection in one particular that Troy of all the cities in the state needs most.

"The real question now is whether Troy can longer afford to be without such an ordinance. The situation, long known both in Troy and outside of Troy, demands action. The spirit of progress in Troy to keep in step with other progressive cities, the predominating sentiment in favor of the ordinance expressed at the hearing, and the public health, particularly proper protec-

tion for the infants of this city, unite as a mighty urge to favorable action on the measure by the Honorable members of the Council."

The people of Troy and the physicians of Rensselaer county are evidently taking a deep interest in matters of public health, for in our issue of February 6th, page 245, we quoted a clipping from the *Troy Times* regarding the chlorination of the city water. When a public health movement is started along one line, it is likely to be extended to other health activities.

---

The *Albany Evening News*, February 9th, carries the announcement of a unique physicians' exchange, and says

"A physicians' central telephone exchange has been organized in Albany, to bring into closer contact Albany physicians and their patients.

"The exchange, one of the first to be organized in this section of the United States, will be located at 86 Jay Street, with executive offices at 82 State Street, R. S. Hill, director, announced today. Service will start March 1, according to arrangements now under way.

"The exchange will fill a long want in Albany," Mr. Hill said today, discussing plans of the organization.

"Many times have we heard of illness or accident where a physician could not be reached in time. The central exchange system corrects all these difficulties. When the system is placed in operation March 1, at every minute of the day we will know where every physician or his alternate can be reached. We will know where every nurse can be located and summoned at a minute's notice.

"There will be a trained telephone operator on three eight-hour shifts every day. When a physician leaves his home, his office or club, he will call the exchange and leave a memorandum where he is going. He will keep the exchange informed of his routine.

"This information will be constantly before the operator. Multiple telephone listings now being arranged will give the physician's home, office and exchange number. A card index also will list his alternates and nurses.

"A patient will be able to locate the physician and a nurse in much less time than heretofore.

"In the event of a catastrophe or serious accident in Albany or nearby it would be possible through the exchange to summon every physician and nurse within a few moments.

"All data relative to medical supplies, etc., also will be listed at the exchange to facilitate action in time of emergencies."

## BOOK REVIEWS

**MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF RENAL DISEASE.** By HUGH MACLEAN, M.D., D.Sc. Second Edition, revised and enlarged. Octavo 110 pages, four colored plates. Phila. and New York, Lea & Febiger, 1924. Cloth, \$2.50.

But few changes appear in the second edition of MacLean's little book on nephritis. The subject is covered in about one hundred pages. It is presented in simple terms. While some of the statements are at least debatable, the reader is impressed, on the whole, with the accurate observation and sound thinking of the author. It should appeal not only to the general practitioner, for whom it was written, but to anyone interested in nephritis. T. H.

**BASAL METABOLISM IN HEALTH AND DISEASE.** By EUGENE F. DUBOIS, M.D. Octavo of 372 pages, illustrated with 79 engravings. Phila. and New York, Lea & Febiger, 1924. Cloth, \$4.75.

An authoritative and comprehensive book on the subject of the basal metabolism and its clinical application has for a long time been greatly needed. The current literature has been exceedingly voluminous, but, nevertheless, no single work of reference has been available. Dr. DuBois has given us a text-book which contains all of the essential facts relating to the clinical study of the basal metabolism. Every phase of this important subject is adequately handled. The writer has attempted to bring basal metabolism out of the realm of pure physiology into the domain of clinical medicine, and he has succeeded.

HENRY M. FEINBLATT

**A STUDY OF MASTURBATION AND ITS REPUTED SEQUELAE.** By JOHN F. W. MEAGHER, M.D., F.A.C.P., Neurologist St. Mary's Hospital, Brooklyn. William Wood and Co., New York, 1924. Price, \$1.50.

With great thoroughness as well as terseness Dr. Meagher has crowded a review of the literature and a practical discussion of this important subject into an extremely small compass. The attitude of the laity as well as of teachers and clergymen, is not always that of the physician and a medical treatise of this kind does much to clarify many factors which are too often veiled in secrecy or enveloped in tradition.

The conclusions reached by the author are interesting, namely that masturbation is not abnormal in children but is distinctly so in adults in whom it shows a psychosexual maldevelopment that sympathy and encouragement are great aids to the patient while censure and punishment are usually harmful. That the problem is more often a psychopathological than a medical and surgical one.

WM. HENRY DONNELLY

**THE CURE OF OBESITY.** By Doctor JEAN FRUMUSAN. Translated from the French by ELAINE A. WOOD. William Wood & Co., New York, 1924. \$2.50.

This is not a scientific volume. It deals at length with the author's own opinions as to the causes of obesity, and he boasts that these opinions are not substantiated by laboratory findings. It seems a little absurd to assert that restriction of diet is not the proper means of approach in treating obesity and then, in a record of treated cases, to outline a diet which even a mild diabetic would think too severe. Nevertheless, the book is interesting and instructive and important in the respect that it repeatedly condemns superalimentation. In a rough way all of the treatments for obesity are described and the author's own system is outlined. Such 'cures' are

not practicable for individuals in this country on account of the lack of electrical equipment. On the whole it may be summed up by saying that it is an interesting little volume not too scientific and not too rational.

L. C. J.

**PEDIATRICS FOR NURSES.** By JOHN C. BALDWIN, M.D., Lecturer in Pediatrics Johns Hopkins Hospital School for Nurses. D. Appleton and Co., New York, 1924.

This textbook is the outgrowth of a series of lectures on Pediatrics given by the author for the past six years at the Johns Hopkins School for Nurses.

Preference is given to the English system of weights and measures as opposed to the metric, since few mothers in this country are familiar with the latter and furthermore practically all scales outside of laboratories are graduated in pounds and ounces.

The same is true of infant feeding as milk is bought in pints and quarts and nursing bottles are graduated in ounces.

Many procedures are employed in the treatment of children which are never used in adults and also many other therapeutic measures are used differently in the child, so that a book on Pediatric Nursing has a definite field of usefulness.

Quite properly the author begins with the Normal Infant and his care, then he takes up the Premature Infant and goes on to a general consideration of Infant Feeding.

Maternal Nursing, Artificial Feeding, and Diet for Older Children are next considered after which the text passes on to Diagnostic Methods and Therapeutics, Diseases Incident to Birth and finally the care of the child in the various diseases.

The care of children forms such an important part of general nursing, and most text books for nurses contain so little matter on the care of children that such a work as this must fill a great need.

WM. HENRY DONNELLY

**GOITER, NON-SURGICAL TYPES AND TREATMENT.** By ISRAEL BRAM, M.D. Instructor, Clinical Medicine, Jefferson Medical College, Phila., Pa. The Macmillan Co., New York, 1924.

The author's wide experience and success in the non-surgical treatment of goiter is the basis of this thorough and complete monograph. Every phase of the subject, anatomy, physiology, pathology, etiology, diagnosis, and classification, symptomatology, and the various signs and signals of insipidity, are definitely described. Goiter is undoubtedly on the increase. Conditions labeled "shell shock," "effort syndrome," "neurocirculatory asthenia," and the like, are, in many instances, early or a typical form of Graves' disease, and often the diagnosis of neurasthenia, hysteria, nervous indigestion, nervous breakdown, phthisis, cardiac neurosis, etc., etc., turn out to be early, formative or borderline cases. The chapters on treatment, hygiene, diet, local measures, and medical treatment are exceedingly precise and instructive, while the chapter on psychotherapy in the management of exophthalmic goiter furnishes practical suggestions in the handling of these difficult cases.

One hundred and fifty reproductions of photographs of goiter cases, most of them "before and after," scattered throughout the four hundred and fifty odd pages of text, help the reader recognize the various types, and enables him to note the improvement, often to complete recovery, careful long-continued treatment produces. A good book for study and reference.

ROBERT ORMISTON BROCKWAY

of shipments will be in force that the practice of substitution among dealers will be wiped out. This has been one of the chief bones of contention among the tongmen in defense of the Great South Bay article. They assert that misleading labels have been used falsely to the discredit of the local product."

## A CASE OF KALA-AZAR IN AN INFANT \*

By MARTHA WOLLSTEIN, M D,

NEW YORK CITY

INFANTILE kala-azar is sufficiently rare, and from the standpoint of international hygiene, sufficiently important, to make the report of a case occurring in an infant in New York City of interest. In 1918, Talbot and Lyon<sup>1</sup> reported a case observed in Boston, a Greek girl, four years old, who recovered after splenectomy, followed by intravenous administration of antimony tartrate. In 1923, Faber and Schuessler<sup>2</sup> detailed the case of an Italian girl, twenty-seven months old, seen in San Francisco, who also recovered after the use of antimony intravenously. The case which is the subject of this paper, the third one of visceral kala-azara infection in children reported in this country, occurred in an Italian boy who died of a complicating noma. The Leishman-Donovan bodies were found in the bone marrow during life and in the liver, spleen and kidneys at autopsy.

The patient was a white boy, twenty-one months old, who had been born in Palermo, Sicily. He was the only child of an Italian physician. The family history was negative and the child had been perfectly well, except for an attack of measles at the age of thirteen months. He was still breast fed at twenty-one months, with the addition of yolk of egg, orange juice and vegetables in small amounts. Ten days before sailing for America, in October, 1923, when the child was eighteen months old, he developed a slight fever, intermittent in type. The temperature was higher at night and in the early morning. This was all that was noticed until five days before he came to the Babies Hospital on January 7, 1924, when a small dark blue spot appeared on the left cheek. This area increased in size until at the time of admission it had become an indurated mass 2 cm in diameter. The skin over it was shiny and discolored. The mucous surface was ulcerated over an area  $1\frac{1}{2}$  by 2 cm. The child was growing thinner and los-

ing appetite. The father said that he was quite certain the child was suffering from Leishmaniasis, having seen the disease in Di Cristina's clinic. He wished to have the diagnosis confirmed by means of a marrow biopsy.

Physical examination showed a well developed and fairly well nourished, but extremely pale boy. The axillary, inguinal, cervical and epitrochlear glands were palpable. The child was not rachitic. There was a foul odor from the mouth. The abdomen was not distended, but the spleen was palpable 5 cm below the costal margin. The liver was not enlarged. There were no abnormal signs in the lungs or heart. Blood examination showed a haemoglobin of 35 per cent, red blood cells 1,400,000, white cells 3,650, polymorphonuclear cells 47 per cent, lymphocytes 25 per cent, transitional and mononuclears 25 per cent, and basophiles 3 per cent. One nucleated red cell was seen to the hundred leucocytes counted. The urine contained a trace of albumin, but nothing else abnormal. Spreads from the ulcer in the mouth showed many fusiform bacilli, a few spirals and many cocci.

Neo-salvarsan was swabbed on the ulceration and was also given intravenously. The child's pallor and anemia remained the same and the ulceration in the mouth seemed to increase. Blood culture gave a negative result.

Two days after admission, Dr Bolling punctured the upper end of the shaft of the left tibia and withdrew some red marrow which was spread on slides. These were stained with Leishman's stain and with Giemsa's stain. Many Leishman-Donovan bodies were found. Some were extracellular, in groups of three to five, some occurred singly, and others were contained in large endothelial cells in groups of five to twelve (Fig 1). One polynuclear leucocyte was seen to contain a single parasite.

The diagnosis having been established, treatment with antimony tartrate was begun. Four cc of a 1 per cent solution were given intravenously. In spite of repeated doses of antimony

† From the Babies Hospital of the City of New York

A TEXTBOOK OF PHYSIOLOGY By H E ROAF, M.D., D.Sc., M.R.C.S., L.R.C.P. Illustrated Longmans, Green & Co., New York, 1924 Price, \$8 50 net.

This book is admirably well written and concise to the point of terseness. It presents many commendable features which should make it of value, not only to the student, but to the general practitioner. It goes a point farther than most books on the subject by giving in detail all experimental data necessary to furnish a proof for the conclusions reached. It stresses particularly the chemistry of the blood and respiration and draws attention to their interpretation in the light of the modern conception of diseased states. In spite of this it is not too highly technical, and should form easy reading matter for the physician, who because of the large demand on his time has been unable to keep up with the more modern trends in physiology.

Of unusual interest is the meritorious effort upon the part of the author to integrate those phenomena which, when studied as separate subjects, are apt to lose their full meaning, and be rather indifferently understood. In this manner the interrelationship between digestion and excretion are clearly brought forward. Likewise the various factors concerned in metabolism are correlated and clearly defined, so that instead of remaining an abstract definition in the mind of the reader, he regards metabolism in the light of the various phenomena which compose it. He thus thinks of the intake of food and the supply of oxygen, though arriving through different channels, as furnishing integral parts to the important processes of cellular activity.

The task of reviewing this volume was a pleasureable one and the reading of it is highly recommended to both student and practitioner.

A. Moss

SAFEGUARDING CHILDREN'S NERVES, A Handbook of Mental Hygiene. By JAMES J WALSH, M.D., Ph.D., Sc.D., and JOHN A. FOOTE, M.D. Foreword by Honorable HERBERT HOOVER. J. B. Lippincott Co., Phila. and London, 1924 Price, \$2.00

The varied and extensive experience of these eminent authors with the medical problems of childhood has enabled them to produce an unusually sensible book on the mental and nervous health of the child. The importance of heredity, rest, fatigue, fears, habits, recreation and the complexes of child psychology is well emphasized, and the entire work is replete with sound, practical advice on the various problems of behavior in childhood, and the management of the backward and the defective child.

Physicians, nurses, teachers, social workers, etc., are urged to read it. Parents, fathers as well as mothers, should be compelled to do so!

ROBERT ORMISTON BROCKWAY

FUNDAMENTALS OF HUMAN PHYSIOLOGY By R. G. PEARCE, B.A., M.D., and J. J. R. MACLEOD, M.B., D.Sc., F.R.S. Assisted in 3rd edition by Dr NORMAN B. TAYLOR. Third Edition The C V Mosby Co., St. Louis, 1924 Price, \$3 50

It is surprising how complete this little book really is when one considers its size. It has something to say of every phase in physiology, though of necessity much abbreviated. Because of this it loses in clearness that which it gains in brevity. It should form an excellent book for a rapid review of the subjects, and should be invaluable for students preparing for examinations, as well as for practitioners who wish to refresh their memories but have not sufficient time to delve into the more exhaustive volumes. As the title states it deals with the "Fundamentals" of human physiology, and these are most interestingly described and on the whole rather readily grasped. The book should have a useful field amongst those desiring a concise, well-written review.

A Moss

A TEXTBOOK OF MATERIA MEDICA FOR NURSES By A. L. MUIRHEAD, M.D., and EDITH P. BRODIE, A.B., R.N. Second Edition C. V. Mosby Co., St. Louis, 1924. Price, \$2.00

Books of this kind, written for the student nurse, are usually too technical to be practical and the student thereby fails to get a fair working knowledge of the subject. This little volume presents the subject in a comprehensible manner, the authors keeping in mind those essentials necessary for the undergraduate which are readily understood and within her grasp. The book is divided into twenty-four short chapters and as each chapter is well suited for an hour's lecture it makes it an ideal book for teaching.

FREDERICK SCHROEDER

LECTURES ON PATHOLOGY (Delivered in the United States, 1924) By LUDWIG ASCHOFF, M.D., Professor Pathologic Anatomy, University Freiburg. Thirty five illustrations. Paul B. Hoeber, Inc., New York, 1924 Price, \$5.00

This small volume embodies a series of selected lectures delivered by the author during his recent tour of this country. The lectures cover a variety of subjects in the domain of tissue change and pathologic physiology. Much original thought founded on observation by himself and his co-workers, and profound knowledge and understanding of the literature is expressed in a clear, concise, masterful way. Correlation of numerous facts published by various investigators have been lined up so that unity has been established where chaos has existed, and reasonable conclusions have been reached. Explanations of pathologic phenomena are built on a basis of logical sequence, and many fine points previously mentioned in an off hand way, have been emphasized, and their importance has been shown.

It is true that in his concept of inflammation, one follows him with some difficulty. His idea is so radical, and he destroys old beliefs and teachings so ruthlessly, that one is left somewhat bewildered. The viewpoint is a new one and gives rise to new thought. It seems as though old things have been expressed in a new language. Anatomic alterations are spoken of in terms of clinical change. His lecture on the reticuloendothelial system is a gem. It sparkles with life, reflecting rays of light from a subject which has been shrouded in darkness. It radiates his views very modestly, simply and convincingly. A very complex and understandable conception of this subject is obtained from its reading.

All in all, it is a refreshing and interesting volume, well worth reading and possessing. It reflects the activities of an unusually brilliant and fertile mind, and is characterized by the personality of its remarkable and noted author.

MAX LEDERER

DEVELOPMENTAL ANATOMY A Text-Book and Laboratory Manual of Embryology By LESLIE BRAINERD AREY, Prof. of Anatomy, Northwestern University Medical School, Chicago. Octavo 433 pages 419 illustrations. Phila. and London, W. B. Saunders Co., 1924. Cloth, \$5 50

The "Developmental Anatomy" by Arey is a text book that can be used both by medical students in their course of Embryology and also by practitioners as a reference book. The developmental history is limited principally to mammalian types. The book is divided into three sections. In the first part, the early stages of development are described. The second part treats of organogenesis according to germ layers, the third division consists of a laboratory manual.

This text excels in the splendid illustrations. The descriptions are clear, well outlined and easily understood. Those who are interested in the developmental anatomy of mammalian forms will find this volume well worth reading.

O. C. P.

gested The *lungs* were congested but showed no consolidation Spreads made from the spleen and from the liver showed numerous Leishman-Donovan bodies

The anatomical diagnosis was Noma, fatty and congested liver, hyperplasia and congestion of the abdominal lymph nodes, hyperplasia of the spleen, visceral Leishmaniasis

#### MICROSCOPIC EXAMINATION

*Spleen*—The capsule and the connective tissue septa were of normal thickness The Malpighian bodies varied somewhat in size but were normal in number Each showed a normal central vessel, the lymphoid cells were not densely packed The pulp spaces were filled with red blood cells, and many of their lining endothelial cells were large and contained Leishman-Donovan bodies, from one to ten in number The pulp was encroached upon by the dilated blood spaces and the pulp cells were not increased in number There were many dark brown pigment granules lying free or within phagocytes (See Fig 3)

FIG. 3

Section of spleen showing Leishman-Donovan bodies within endothelial cells lining pulp sinus.  
X 1,000

*Liver*—The capsule was not thickened The inter- and intralobular vessels were congested In many lobules the cells around a central vein had undergone pressure atrophy as a result of the congestion of the vessels Many other cells contained droplets of fat, and very few of the liver cells remained normal The connective tissue was not increased in amount Many of the endothelial cells of the liver capillaries were swollen and contained Leishman-Donovan bodies from one to six in number A few polymorphonuclear leucocytes were seen in the liver capillaries carrying one or two parasites (See Fig 4)

FIG. 4

Blood capillary of liver in which a pealed endothelial cell (a) contains a group of Leishman-Donovan bodies, (b) liver cells, fatty

*Kidneys* — The kidneys showed a moderate amount of degeneration and peeling of the epithelial cells of the convoluted tubules The glomeruli were quite normal All the blood vessels were filled with red blood cells The lesion was one of congestion and moderate epithelial degeneration of the cortical tubules In endothelial cells lining the small blood vessels, Leishman-Donovan bodies were present, both in the cortex and in the medulla of the kidney Fig 5 shows the parasites in a cell lining a capillary within a glomerulus

FIG. 5

Section of kidney showing glomerulus, (a) Leishman-Donovan bodies within an endothelial cell, (b) capillary blocked with cocci.

*Colon*—The colon showed loss of superficial epithelium, but the deeper portion of the mucosa with its glands was intact. The submucosa was

FIG 1

Marrow obtained by puncture during life, intracellular (a) and extracellular (b) Leishman-Donovan bodies

and two transfusions with blood from the father, the child grew steadily more toxic, the leucopenia persisted, the noma increased in size and finally perforated the cheek on the day before death. This occurred two weeks after admission to the hospital, and three and three-quarters months after the first symptoms had been noted.

The temperature chart (Fig 2) shows the irregularity of the fever, which ranged between  $102^{\circ}$  and  $104^{\circ}$  for the greater part of his stay in the hospital.

Autopsy through an abdominal incision was permitted. The anatomical findings were as follows:

The body was that of a fairly well nourished male white child. There was a perforating noma of the left cheek, incised transfusion wounds in

the anterior cubital fossae and a puncture wound over the upper end of the left tibia. No skin eruption was present. The peritoneum was normal. The spleen weighed 164 gm and measured 15 cm in length, 8 cm in width and 4 cm in thickness. The capsule was smooth, dark blue in color. The whole organ was very soft and on section the pulp was dark red and almost friable. The Maphighian bodies were not increased in size. The liver weighed 580 gm and extended 5 cm below the costal margin. Its capsule was smooth. The substance was firm, mottled yellow and red, moderately congested and slightly fatty, and without connective tissue increase. The gall bladder and ducts were normal. The stomach was normal in size, its mucosa was congested and there was a slight amount of mucus present, no food. The congestion was attributed to repeated lavage. The intestines were normal throughout. The mesenteric lymph nodes were enlarged, several measured 0.75 cm in length and were pink in color. The small lymph nodes in the mesentery close to the colon wall were all hemorrhagic in color, brilliant red, and measured 3 mm in length and 1 or 2 mm in width. All the retro-peritoneal lymph nodes showed the same hemorrhagic, swollen condition. The inguinal nodes on both sides were pale and normal in size. The testicles were normal in color and consistency. The kidneys weighed 48 gm. They were red, the markings were slightly blurred and the capsule was free. The ureters and bladder were normal. There was a large amount of urine in the distended bladder. The suprarenal glands weighed 8 gm. Their medulla was distinctly con-

FIG 2 Temperature Chart

blood Recently Young and Van Sant<sup>16</sup> have described a method by which positive cultures of Leishman-Donovan bodies were obtained in about 90 per cent of untreated cases studied in Pekin

The method of transmission is still a mystery, and while fleas, bed bugs and mosquitoes have been accused of carrying the parasites, scientific proof is lacking that any of these insects is really involved<sup>18</sup>

The method of action of the parasite, once it enters the human host, is apparently clear from the microscopic studies That is, the organisms penetrate endothelial cells, especially those lining the blood vessels These cells burst when they become too distended with parasites, which are then set free into the blood stream Leucocytes, especially polymorphonuclears, take up the free parasites and carry them to all viscera, apparently depositing them anew in endothelial cells Red cells would seem to be unmolested by the organisms As Shortt has pointed out, Leishmaniasis is essentially a disease of endothelial tissue By destroying the cells in which it multiplies, the organism gradually causes cell destruction and a toxemia which leads to anemia, asthenia and death

Ray<sup>13</sup> described a reaction which shows a turbidity and flocculation of the blood on the addition of distilled water The test was positive in our case, when controlled by the serum from four other children in the hospital free from kala-azar

#### TREATMENT

In 1913, Gaspar Vianna<sup>14</sup> first used tartar emetic in treating cases of South American cutaneous Leishmaniasis Two years later, Di Cristina and Carona<sup>15</sup> treated children with visceral Leishmaniasis by means of intravenous injections of antimony tartrate and obtained excellent results, the drug acting as a specific In our case, the treatment was begun only after the noma had progressed and added to the toxemia The fact that the postmortem spreads made from the liver and spleen showed many less Leishman-Donovan bodies than did the marrow spreads made before treatment was begun, suggests that the antimony had acted on these organisms, and that the secondary infection from noma was the real cause of death Young and Van Sant have pointed out that after 12 mg of antimony per kilo of body weight had been administered, they were unable to find cultivable Leishman-Donovan bodies in the peripheral blood of patients studied in Pekin

#### SUMMARY

A case of visceral Leishmaniasis or kala-azar in an infant born in Palermo is reported It is the third American case recorded in a child, and the first one to come to necropsy These three children came to the United States from the endemically infected regions about the Mediterranean coast (Greece and Italy) and lived in Boston, San Francisco and New York, respectively

Noma of the cheek appeared three weeks before death

During life, Leishman-Donovan bodies were found in the bone marrow After death Leishman-Donovan bodies were found in spreads from the spleen and liver and in sections from the liver, spleen and kidneys

edematous and the muscle and serous coats normal

*Suprarenal* — The suprarenal gland showed intense congestion of the vessels of the medulla, and this congestion extended into the cortex

Leishman-Donovan bodies were found in the bone marrow, liver, spleen and kidneys, but not in the colon nor suprarenal glands

The pathological changes were similar to those which have been described by other observers

In the three adult autopsies described by Christophers<sup>3</sup>, the liver was not enlarged. Microscopically the dilated intralobular capillaries had large cells, the nature of which Christophers found it difficult to determine. Shortt<sup>4</sup>, describing the organs of rhesus monkeys successfully inoculated with kala-azar by means of liver and spleen emulsions from a fatal case in an adult, found the bodies in endothelial cells of capillaries and in Kupffer cells, not in the liver cells themselves. In the human spleen, Christophers found the parasites more numerous than in the liver, and always intracellular. In the monkey, Shortt found hyperplasia of endothelial cells of the spleen capillaries and the blood sinuses, with many parasites. Christophers found the organisms in red bone marrow, but less numerous than in the spleen and liver. They were contained in macrophages, occasionally in polymorphonuclear leucocytes and myelocytes, but never in red blood cells. In the experimental disease, Shortt found the parasites within a certain number of leucocytes in spreads made from the spleen, but the endothelial cells are the chief carriers of the Leishman-Donovan bodies. Christophers found organisms in the spreads from the ulcers present in the large intestine. Di Christina<sup>5</sup> described the mesenteric and retroperitoneal nodes as "cyanotic," just as were those in our case.

Shortt found that the experimental disease in monkeys is essentially the same as in human beings, a disease of endothelial tissue and especially of vascular endothelium.

The fact that Shortt<sup>6</sup> was successful in cultivating Leishman-Donovan bodies from the urine of an adult case and that the kidney sections from our case showed the organism, is of great importance from the standpoint of hygiene and epidemiology.

We found no parasites in sections of the colon, which was not ulcerated. Jemma and Di Christina<sup>7</sup> found ulcerative colitis at necropsy in children who died of kala-azar. Parasites have been demonstrated in the lymph nodes draining ulcers of the colon<sup>7</sup> and of the skin<sup>3</sup>. Although the Leishman-Donovan bodies have been described

as being present in the feces, Laveran points out that the bacteria in the intestinal tract would soon disintegrate the parasites and that their presence in the intestinal tract could not do permanent harm from an epidemiological standpoint.

Leishmaniasis is of two varieties, cutaneous or tropical boil, and visceral or kala-azar (black fever)<sup>17</sup>. The disease has been known for a long time in its endemic areas in India, China and along the Mediterranean Coast. Authentic cases, however, date only from the discovery of the organism by Leishman<sup>8</sup> and Donovan<sup>10</sup>, in 1903. The organism is a protozoon, class mastigophora, genus *Leishmania*. It develops a flagellum only in culture media outside of the body. Within the vertebrate host it develops within cells of the endothelial type and in the leucocytes, dividing by binary fission.

The first case to be described in a child was that which Laveran and Cathoire<sup>11</sup>, published in 1904, in an infant seven months old, a native of Tunis. Since then many cases have been studied and published from both the northern and southern coasts of the Mediterranean. In Sicily, Leishmaniasis is endemic in the region of Messina and Palermo. Di Giorgio<sup>12</sup> saw forty-one cases at the clinic for sick children in Palermo during a single year. The disease has been observed in children in Naples and even in Rome<sup>1</sup>. It is interesting in connection with the present case that he was born in Palermo, one of the endemically infected areas of the Mediterranean coast.

The incubation stage of kala-azar is not definitely known because of the insidiousness of the onset, but it probably ranges between six weeks to three months<sup>7</sup>. The only symptom in the early stage is a mild irregular fever which may be intermittent or remittent. Splenomegaly, anemia and emaciation develop gradually after a period of months. The blood shows a leucopenia, with diminution in the polynuclear cells, low hemoglobin and diminished red cells. Noma is a complication of the late stage and usually proves fatal. It has been noted in 8 per cent of cases occurring in Italy and in 16 per cent occurring in Tunis<sup>8</sup>. The duration of the disease is an extended one. Six months is short and one and a half to two years is not exceptional. In our case the duration was from about the 1st of October until the 20th of January, a period of three months and three weeks, or 112 days. This would seem to be unusually short, providing the date of origin was rightly given.

The organisms have been found in practically every organ of the body and in the peripheral

clusions already reached by the authors mentioned. The parietal peritoneum, over its anterior surface and over the lateral surfaces explored, responds to pressure or scratching stimulation with a sharp, stitch-like pain that is localized by the patient within half an inch of the points of contact. As we reached the hitherto unexplored region of the under surface of the diaphragm we found the pain was referred either to the subcostal region or the neck, depending upon whether the outer margin or the central part of the diaphragm was stimulated. Exactly the same phenomena of referred pain were observed as from stimulating the upper or plueral surface of the diaphragm.

#### CLINICAL OBSERVATIONS

The pain of an ordinary parietal pleurisy is familiar to everyone. It is only necessary to point out that this pain is never referred to a distant part, but is quite sharply localized.

Diaphragmatic pleurisy is far more common, especially in association with pneumonia of the lower lobes, than is usually thought. Probably ten per cent of lobar pneumonia patients develop abdominal pain and tenderness and about half this number complain of referred pain in the neck. The only difference between the experimental and clinical picture is that the latter exhibits an associated hyperesthesia of the skin and a muscular contractibility in addition to the subjective pain.

In the study of our patients with peritonitis

we also find evidence to support the view that parietal peritonitis manifests itself by a sharp pain located over the area inflamed and not referred to distant parts.

On the other hand we have noted numerous cases of subphrenic abscess, perisplenitis and other forms of subphrenic inflammation where the pain was referred to the abdomen, to the neck or to both places. Cough and deep inspiration tend to aggravate this pain.

In obscure diseases the development of neck pain will often establish the site of the affection.

The referred pain of diaphragmatic pleurisy is often mistaken for an abdominal disease. We have records of many cases diagnosed and operated upon for appendicitis, perforated gastric ulcer, gallstones and renal calculus, that have shown no abdominal pathology, but have later developed the signs of pleurisy or lower lobe pneumonia.

The history of chill, cough, painful respiration, and the findings of a high leucocyte count, rapid breathing, herpes and even slight congestion at the base of the lung should prevent these mistakes. If the neck pain happens to be present the diagnosis is made. I know of no abdominal condition that will produce the phrenic nerve pain in the neck excepting irritation or inflammation of the diaphragm, or the presence of free gas worming its way under the diaphragm. It is often stated that this pain may arise from ulcer of the duodenum or chelecystitis, but our experience contradicts this, unless there is a complication involving the diaphragm also.

## HIGH BLOOD PRESSURE TREATED WITH SENSITIZED COLON VACCINE

By JOSEPH F BICAK, M.D.,

NEW YORK CITY

THE cases cited below were taken without any selection whatever, and treated by subcutaneous injection of a sensitized vaccine of the colon bacillus, 2,000,000,000 to the c.c. The injections varied from one-half to five minims, the first was usually two, and were given every two to seven days. The mildest cases were given only the vaccine. The others received thyroid, oxgall and bacillus acidophilus and a few of the most severe cases received small doses of nitroglycerine.

The pressure was taken in the sitting position and every effort was made to make the patient feel at ease. Only the systolic pressure will be noted as the diastolic improved in a corresponding manner in most of the cases and became normal in all in which the former did.

Case 1. Mrs. A. S., 35, U. S., family history negative, came May 14, 1923, with the statement that she had diabetes for two years,

and suffered from dizziness, headaches, palpitation of the heart and tiredness. The urine contained 144 ozs. sugar in twenty-four hours and a marked trace of albumen. The pressure was 190. After six injections, amounting to ten and a half minims, the pressure was 156 on June 12. She did not return after this. All the subjective symptoms improved with the pressure.

Case 2. Mr. H. R., 56, U. S., family history negative, had chronic bronchitis with occasional attacks of asthma, and low blood pressure for many years. He dropped out of sight for a long time and then reappeared on May 10, 1923, with the statement that he was rejected for life insurance on account of high blood pressure. The urine showed a trace of albumen and numerous calcium oxalate crystals. His pressure was 190. He received ten injections, amounting to eighteen minims, the last one on June 30. On July 17, the urine

## ORIGIN AND RADIATION OF PAIN IN THE SEROUS MEMBRANES AND ITS VALUE IN DIAGNOSIS \*

By JOSEPH A CAPPS, M D

CHICAGO ILL.

**O**F all the subjective sensations described by a patient, pain easily occupies the first place. It may be equally true that the interpretation of pain, its origin, its localization and its radiation, yields more information to the physician than any other single symptom. This applies with especial force to the understanding of disease processes in the thorax and abdomen, where the lesion is deep seated and often obscure.

For a number of years we have been engaged in a study, along experimental and clinical lines, of the pain sensation in the serous membranes of the thorax and abdomen.

The experimental observations in the thorax have been carried out in patients with a large effusion, either exudates or transudates, where the lung was retracted. A hollow trocar is inserted either in the subscapular, axillary or anterior region of the chest and before draining off the fluid a long silver wire is introduced through the canula. Under favorable conditions it is possible to bring the end of the exploring wire in contact with the visceral pleura, the parietal pleura, the diaphragmatic pleura and the lower portion of the pericardium. A brief summary of a large series of experiments is as follows:

(1) The visceral pleura gives no pain response to scratching or pressure with the wire point.

(2) The parietal pleura exhibits a prompt response to stimulation, the pain being sharp, stitch-like, and localized with remarkable accuracy over the spot irritated.

(3) The diaphragmatic pleura seems incapable of pain localization in the region of the irritated spot. The pain elicited is radiated in two different directions, depending upon the area irritated. When the stimulation is over the outer margin of the diaphragm the pain is referred to the lower costal and subcostal region, and if the stimulation is intense, to the lower abdominal region of the same side. The pain, unlike that of the parietal pleura, is dull aching in character, and upon removal of the wire passes off gradually like the toothache that disappears after the dentist desists from hammering a filling. When, on the other hand, the central part of the diaphragm is irritated the patient refers the pain to the region of the neck, usually to a spot over the trapezius ridge, less often under the mastoid, in the anterior triangle of the neck or over the coracoid process. The quality of the pain differs from the referred pain in the abdomen in being sharply localized and more acute.

We may readily understand the mechanism of the abdominal pain by recalling that the lower six thoracic nerves penetrate the diaphragm. The sensory filaments of these nerves, unable apparently, as a result of disuse or lack of education, to give expression to painless sensations in the structure itself, carry afferent impulses to the posterior portions of the cord and create foci of irritation. These foci in turn give rise to pain along the nerve fibres of the corresponding segments which supply the skin and abdominal wall from the level of the ensiform to the groin.

The central portion of the diaphragm is supplied by the phrenic nerve, which is merely a fusion of fibres from the third, fourth and fifth cervical nerves, that has been drawn down with the descent of the diaphragm during the embryonal life. The phrenic nerve endings, like wise, convey impulses to their respective cervical roots in the spine and find expression in the segments of the skin and underlying tissues supplied by the third, fourth and fifth cervical sensory nerves. The relative frequency of pain over the trapezius region, supplied by the fourth segment, probably is due to the fact that in most individuals the greatest number of afferent fibres in the phrenic nerve enter the cord at the level of the fourth spinal roots.

Stimulation of the lower portion of the pericardium, near its union with the diaphragm, also elicits the phrenic nerve type of referred pain in the neck.

The pain sense of the peritoneum had been studied by Mackenzie, Lennander and Ranstrom by instrumental irritation of the parietal surface during the course of laparotomies performed under local anæsthesia. They agreed that such irritation produces pain of a sharp character and well localized, whereas, such irritation of the mesentery or intestines causes no pain. Their field of exploration was limited, however, to the immediate region of the incision.

Experimental investigation in the abdominal cavity is beset with peculiar difficulties and dangers. The intestines and omentum impede the movement of a wire and there is always a possibility of injury. These objections were surmounted by injecting two to three litres of sterile air in suitable cases with a thin abdominal wall. The air, rising to the top, leaves a clear space for the movements of the wire. Furthermore, the air fills the space between the liver and diaphragm, thus allowing the exploration of the peritoneal surface of the diaphragm.

The results obtained by Coleman and myself by this method confirmed and extended the con-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester, April 23, 1924.

to normal and more than four times that amount failed to lower it any more

Case 14 Miss B H, 49, Ire, family history negative, had been treated for hypertension two years before, came with the statement that she was just out of hospital, where she had a pressure of 300 on entrance and 260 on leaving, after a stay of nine weeks. She complained of headache, had a trace of albumen in the urine, and a pressure of 262. On Sept 23, 1923, after twelve injections, amounting to thirty-six minims, the pressure was 210. She had been in bed during this time and received an injection every two days. She was then allowed to get up, and all improvement stopped, the pressure ranging from 214 to 228. It was found that the patient, very stout, was gaining weight. It took some time to get the patient to cooperate. She also had several serious causes of worry and did not sleep well. Luminal was given and finally the patient began to eat less. Then the pressure dropped from 220 to 175 in four weeks. Treatment was to be continued.

Case 15 Miss R M, 46, U S, family history negative, came Aug 4, 1923, complaining of headache. The pressure was 152. On Oct 24, after eight injections, amounting to fourteen and a half minims, and given at irregular intervals, the pressure was 126, and the headache was gone.

Case 16 Mrs H R, 52, U S, husband was also treated for hypertension this year. Arose on the morning of Sept 17, 1923, and soon after was overcome by sudden weakness falling to the ground. When seen she said that she had a "trembling feeling all over the body." The pressure was 182 and an injection of two minims was given. Next day the pressure was 138.

Case 17 Mrs E B, Ger, 73, family history negative, complained of dizziness. There was a trace of albumen in the urine. She came on Sept 17, 1923, with a pressure of 182. On Sept 27, after three injections, amounting to six and a half minims, the pressure was 160 and the dizziness gone. She did not return after this, although she said that she felt better after each injection.

Case 18 Mrs L B, 63, Ger, family history negative, came Sept 22, 1923, complaining of dizziness, weakness, irritability, and seeing "looking-glasses all around her." The pressure was 210. By Nov 12, after eleven injections, amounting to thirty-three minims, the pressure was 152. All the symptoms of which she had complained were gone before this.

Case 19 Miss H K, 15, U S, had acute inflammatory rheumatism, involving the heart, at five, followed by chorea, and had rheumatic symptoms ever since. She had been treated

for high blood pressure for the past seven months, and had a headache on rising every morning. There were occasional hyaline casts in the urine. The thyroid was somewhat enlarged. She called on Oct 25, 1923, with a pressure of 148. After nine injections, amounting to nineteen minims, the pressure was 132 on Nov 28. The headache came about once in three days and she looked much better.

Case 20 Mrs J F, 50, Swed, came Oct 26, 1923, complaining of occasional headaches. The pressure was 166. Nov 12, after five injections, amounting to eight minims, it came down to 117. She looked much better, and said she felt much better and that she had not had a headache for "some time."

Case 21 Mrs E K, 63, Ire, ailing for years and probably had high pressure for years, but it is not possible to get definite information on this point. She was seen for the first time on Sept. 26, 1923, and complained of dizziness, recent deafness, cardiac pain, dyspnoea, and insomnia. She had arteriosclerosis, very much hypertrophied heart, very irregular pulse, edema of the lower extremities and ascites. There was a trace of albumen and hyaline casts in the urine. She had been in one of the large hospitals of this city for three months, had no edema on entrance but much of it when seen for the first time, which was three days after leaving. Evidently her condition grew worse while resting in the hospital. During her stay there she was told that one of her kidneys was bad. The pressure was 195. She received thirteen injections, amounting to twenty-five minims, the last one on Nov 7. On Nov 29, the pressure was 150 (diastolic 96—had been 134). In extreme cases like this it might be well to begin in the same way as in the others, but as soon as the pressure drops ten points, the vaccine should be very much reduced or stopped temporarily. It would be well to give a few minims of adrenalin solution with it except in diabetic patients. She was still very ill and the only thing that can be claimed in the case is that the pressure was reduced as in the others, and that if she had received the treatment before the vital organs became seriously affected her life would have been saved.

Case 22 C B, 57, Ire, smokes excessively. Came Nov 6, 1923, with a pressure of 170. Three weeks later, after three injections, amounting to six minims, the pressure was 160.

Case 23 L A, 63, U S, came Nov 14, 1923, complaining of headaches. The pressure was 173. Two weeks later, after two injections, amounting to four minims, the pressure was 156, and she looked and felt better.

contained no albumen and on July 19 the pressure was 148. He stated that he felt better than for many months. On Oct 8, the pressure was 142, showing a further gain without any more treatment.

Case 3 Mr F V, 25, U S, family history negative, came May 21, 1923, with the statement that he was rejected for life insurance on account of high blood pressure. His urine showed a trace of albumen. The pressure was 155. He received four injections, amounting to five minims, the last one on June 22. On July 9, his pressure was 122, and he stated that he felt better.

Case 4 Mr M J, 70, Ger, family history negative, had high pressure for one year. The urine shows a trace of albumen. He complained of dizziness, and the pressure was 179. He came on April 14, 1923. After seven injections, amounting to ten and a half minims, the last one given on May 26, the pressure was 146, and the dizziness was gone.

Case 5 Mr F B, 56, Bohemia, family history negative, had a mild cerebral hemorrhage two years before and the face and voice still show a trace of its effects. The urine showed a trace of albumen and occasional hyaline casts. The pressure was 202 on April 30, 1923, when he came for the first time. After receiving eleven injections, amounting to thirty-two minims, his pressure was 163 on July 2, and he said that he felt better than for months. He then went out of town and returned on Oct 16, with a pressure of 180, showing that after more than three months, he still retained more than half of the gain. After further treatment, on Nov 24 the pressure was 150, but the diastolic was still 118 in this case.

Case 6 Mrs E B, 47, U S, family history negative. She said that she had hypertension for two years and complained of headaches, and cardiac pain. Her face was flushed when she called for the first time, on Sept 25, 1923, and the pressure was 208. On Nov 6, after eight injections, amounting to twenty minims, the pressure was 164, the face no longer flushed, the headaches and cardiac pain gone and she said that she felt much better.

Case 7 Mr S J, 71, Rus, family history negative. Came June 10, 1923, complaining of very severe cardiac pain on the slightest exertion. He had great cardiac hypertrophy and arteriosclerosis, and a trace of albumen in the urine. The pressure was 192. On June 26, after five injections, amounting to ten and a half minims, the pressure was 176.

Case 8, Miss V H, 25, U S, family history negative, suffered for eight years from difficulty in breathing when lying down and on exertion, cardiac pain, very frequent headaches

and tiredness. Her face was flushed and there was a trace of albumen in the urine. She came on May 17, 1923, with a pressure of 145. On July 5, the pressure was 120, after seven injections, amounting to eight and a half minims. The face was no longer flushed and she felt "better than for years." She had complained of her symptoms out of all proportion to the pressure, but they were all improved very much as it came down, though not entirely relieved. Since then she received an injection almost every week to Nov 22. The symptoms continued to improve.

Case 9 Mr L B, 34, U S, father had a stroke of apoplexy. The urine showed a marked trace of albumen. On May 13, 1923, the pressure was 155 and an injection of mjs was given. A week later, the pressure was 138.

Case 10 Mrs B S, 54, U S, family history negative, came May 28, 1923, with a pressure of 170. She received a total of seven injections, amounting to sixteen minims. On Aug 7, twenty-two days after the last injection, the pressure was 146.

Case 11 Miss M C, 43, Ire, family history negative. She came Aug 2, 1923, complaining of headaches. The face was flushed and there was 9 per cent sugar in the morning urine, with a trace of albumen and occasional hyaline casts. The pressure was 195. After six injections, amounting to eleven minims, and given every two to four days, the pressure was 168. She neglected treatment for two weeks, and the pressure was 180 on Sept 3. Three more injections, amounting to three minims, brought it down to 160 on Sept 11. After another absence of twenty-four days, it was 168 on Oct 5.

Case 12 Mrs I F, 63, Rus, family history negative, had hypertension for five years. She and her daughter seemed to be under the impression that it was usually around 300. She complained of dizziness, weakness, dyspnea and constipation. She called on Sept 27, 1923, with a pressure of 292, and received an injection of two minims, and was directed to go to bed immediately. Two days later, the pressure was 252 and she looked much better. Treatment was discontinued, as she was obliged to go to her own home at a distance.

Case 13 Mr C G, 53, family history negative, was treated for hypertension before, had sciatica, but was able to work. Came Sept 4, 1923, with a pressure of 170. Five injections, amounting to nine and a half minims, and given one week apart, brought the pressure down to 138. After this injection of two to two and a half minims twice a week for ten weeks, failed to bring it down any more. It took nine and a half minims to bring it down.

of the cartilage and thickening of the sinovial membranes and at times adhesion of the opposing surfaces. In certain cases, the X-ray suggests, if not proving conclusively, that the primary process is in the soft parts. Inflammation, suppuration, caseation and sclerosis may enter into the pathology of the involved areas. In case of doubt, the production of a focal tuberculin reaction usually establishes the diagnosis.

The *syphilitic* joint likewise calls for a careful search of the patient as a whole for systemic evidence of the disease. Locally, there is the history of a chronic onset and the aid afforded by the X-ray, the characteristic subperiosteal budding and resorption areas. Moreover, the bone changes are rarely limited to the joint, but usually involve the shaft, both on the periosteal and medullary surfaces which when advanced may result in a rarifying or a thick ivory ossification. Nodes may form at the epiphyseal lines of the shafts of the long bones and grow to a size that it palpable and even visible, when congenital forming a collar around the bone. An important finding both in acquired and congenital syphilis, which so far as we know has not been recognized, and that is oftentimes of very great value in deciding the diagnosis, is the occurrence on the phalanges of the subperiosteal budding and resorption areas without necessary relation to any other syphilitic pathology. These may be so slight as to be either overlooked or disregarded till their diagnostic importance is realized. Even with a negative Wassermann reaction, so frequent with bone syphilis, their occurrence is a definite indication of syphilitic infection.

Charcot's joint, nearly always monarticular, is a special form of syphilitic manifestation that may involve the shoulder, elbow, wrist, ankle or other large joint, but most frequently the knee. It commonly develops suddenly, in a few hours, and without apparent cause, the joint swelling, fluid gathers in large amount (hydrops articuli), the ligaments relax, so that there is excessive mobility, all without fever, pain or signs of inflammation. The bones and cartilages may be rapidly destroyed and spontaneous dislocation or even fracture is apt to occur. Muscular atrophy is marked.

Another form of syphilitic joint is the monarticular adhesive type in which the opposing synovial surfaces are adherent with loss of motion. The ankylosis may be due only to fibrous adhesions (partial), to chondrification of the fibrous tissue (incomplete) or to ossification (complete). When syphilitic, such an arthritic joint must be differentiated from similar conditions due to trauma, usually monarticular, including "dry joint" or from aseptic inflammation associated with other systemic conditions.

*Gonorrhoeal* arthritis is usually ushered in as an acute process. Either the synovial membrane is mainly affected or sometimes a bursa and the effusion is intra-articular, or more commonly periarticular structures are the seat of the affection and the effusion is around rather than within the joint. It may become sero-purulent or purulent. Either form tends to become chronic and resistant to treatment. It is mono-articular, the osseous tissues are not involved. The swollen joint is a feature of the clinical picture.

An *infectious* arthritis in which the invading organism is not specific generally begins more or less acutely and commonly is the sequella of an acute process, the location of which is ordinarily clearly indicated by the clinical history. As an example, the arthritis following tonsillitis may be cited. Any other local infection may serve as well as the source of the infection or toxæmia that underlies the arthritis. In the great majority of instances, it is polyarticular, although some of the joints may be only transiently affected, the arthritis reaching a subacute or chronic stage in a relatively small number of joints. When the original focus is less acute, the arthritic manifestations are correspondingly more gradual in their onset. The process ordinarily involves all the joints to be affected in a comparatively short time, the tendency of extension to other joints being less than in some other forms of arthritis. The formation of sero-fibrinous exudate, characteristic of infection regardless of location, applies to the form of arthritis under consideration, in consequence of which there is thickening of the fibrous and synovial membranes with formation of adhesions, even to the obliteration of the synovial cavity. If the onset is acute, the adhesions predominate, if chronic with low grade inflammation, the thickening of the membranes is more marked. In certain instances, actual bacterial invasion of the joint may be demonstrated, in others, it has been held that the result is entirely brought about by the action of bacterial toxins. The X-ray affords valuable information in establishing the pathological anatomy more or less characteristic of infectious arthritis.

The organisms isolated include more commonly varieties of the staphylococcus and the streptococcus groups, occasionally the typhoid bacillus, the pneumococcus or even the diphtheria bacillus. Other organisms have also been described, to some of which special names have been ascribed.

*Still's* disease is a term applied to a form of chronic polyarticular arthritis, generally believed to be infectious, and occurring before the age of fifteen years. Not only are there enlarged joints, but marked glandular involvement, together with enlargement of the spleen, and, as a general rule, marked muscular atrophy and wasting. It should not be confused with non-infectious polyarthritis to which childhood is not immune, but which is

Case 24 D M, 55, Ire, came Nov 27, complaining of headache and dizziness. The urine contained 2 per cent albumen and frequent hyaline casts. The pressure was 252 and two minims were given. Two days later the pressure was 240 (the diastolic was reduced from 150 to 140). He said that he felt much better.

Improvement was prompt in all the cases and marked in most. In the two cases of diabetes the pressure improved as well as in the rest. Apparently the cause of the hypertension was the same as in the others. Several of the patients became uncomfortable when the pressure came down very fast, but this was very

temporary and the treatment was soon resumed. The belief that hypertension is caused by the toxins of the colon bacillus in most cases seems to be justified by the following reasons:

1 The hypertension was improved in all the cases cited by the injection of sensitized colon vaccine.

2 When the pressure reaches normal further treatment with the vaccine does not reduce it any more.

3 Dizziness is a common symptom of hypertension as well as such conditions as constipation, indigestion, etc., in which one would expect more of the toxins of the colon bacillus to be absorbed from the bowel.

## THE CHRONIC ARTHRITES \*

### THEIR DIFFERENTIAL DIAGNOSIS AND TREATMENT, WITH SPECIAL REFERENCE TO THE RELIEF OF PAIN

By BENJAMIN P RILEY, M D, and E E SMITH, Ph D, M D,

NEW YORK, N Y

IN no part of medicine have names been applied more ambiguously than in the differentiation of the arthritides. The reasons for this are associated with the historical development and our present limited knowledge of the subject. What was formerly regarded as an entity is today recognized as a group of more or less allied clinical manifestations dependent upon varied underlying etiology and pathology. Then, too, the terminology is a combination of contributions from the viewpoints of different specialties without the controlling and co-ordinating influence of a single broad comprehensive aspect. It is largely for these reasons that there is confusion at the present time. As we use the term, chronic arthritis is applied to chronic diseases of the joints in their varied manifestations. With the laity and with some practitioners, the entire group frequently continues to be referred to as chronic rheumatism. At the present time, this term should at least be limited to diseases of the joints due to the virus or organisms that are the cause of rheumatic fever.

Any classification that is at present possible must be irrational, for we have not sufficient knowledge of etiology, pathology or clinical history to make any one of these the basis of a scientific differentiation. However, by consideration of the combined knowledge available in all of these aspects, more or less definite types are indicated, the recognition of which must for the present serve for classification.

On the basis of etiology, we would first distinguish infectious and non-infectious chronic

diseases of the joints, with a classification of the former based in a measure on etiology, and of the latter, based on pathology, as follows:

#### Infectious

Tubercular

Syphilitic

Gonorrhoeal

So-called "rheumatic" infections

Still's disease

#### Non-infectious

Atrophic type (rheumatoid)

Hypertrophic type (osteo)

Villous

Gout

It is at once seen that diagnosis is dependent not only on a knowledge of the joint itself but of the patient as a whole, and further, what of necessity follows, that in most instances treatment is indicated likewise for the patient, rather than merely the joint or joints involved.

*Tuberculosis* of the joint more frequently affects a single joint, though not rarely two or more joints are involved. The condition many times is primarily a peri-arthritis, the invasion of the joint, if at all, being due to extension of the disease. It is a matter of dispute whether the joint proper is ever the beginning of the process. While more prone to occur in the very young, before ossification is complete, adults are not immune. The spine, the hip, the knee, the ankle, the elbow, the wrist and the shoulder are the order of frequency of joint involvement. The local manifestations of the arthritic joint are destructive areas in the adjacent bone and, where extension to the joint has occurred, destruction

\* Read before the Medical Association of the Greater City of New York, October 20, 1924.

of the cartilage and thickening of the sinovial membranes and at times adhesion of the opposing surfaces. In certain cases, the X-ray suggests, if not proving conclusively, that the primary process is in the soft parts. Inflammation, suppuration, caseation and sclerosis may enter into the pathology of the involved areas. In case of doubt, the production of a focal tuberculin reaction usually establishes the diagnosis.

The syphilitic joint likewise calls for a careful search of the patient as a whole for systemic evidence of the disease. Locally, there is the history of a chronic onset and the aid afforded by the X-ray, the characteristic subperiosteal budding and resorption areas. Moreover, the bone changes are rarely limited to the joint, but usually involve the shaft, both on the periosteal and medullary surfaces which when advanced may result in a rarifying or a thick ivoryoid ossification. Nodes may form at the epiphyseal lines of the shafts of the long bones and grow to a size that it palpable and even visible, when congenital forming a collar around the bone. An important finding both in acquired and congenital syphilis, which so far as we know has not been recognized, and that is oftentimes of very great value in deciding the diagnosis, is the occurrence on the phalanges of the subperiosteal budding and resorption areas without necessary relation to any other syphilitic pathology. These may be so slight as to be either overlooked or disregarded till their diagnostic importance is realized. Even with a negative Wassermann reaction, so frequent with bone syphilis, their occurrence is a definite indication of syphilitic infection.

Charcot's joint, nearly always monarticular, is a special form of syphilitic manifestation that may involve the shoulder, elbow, wrist, ankle or other large joint, but most frequently the knee. It commonly develops suddenly, in a few hours, and without apparent cause, the joint swelling, fluid gathers in large amount (hydrops articuli), the ligaments relax, so that there is excessive mobility, all without fever, pain or signs of inflammation. The bones and cartilages may be rapidly destroyed and spontaneous dislocation or even fracture is apt to occur. Muscular atrophy is marked.

Another form of syphilitic joint is the monarticular adhesive type in which the opposing synovial surfaces are adherent with loss of motion. The ankylosis may be due only to fibrous adhesions (partial), to chondrification of the fibrous tissue (incomplete) or to ossification (complete). When syphilitic, such an arthritic joint must be differentiated from similar conditions due to trauma, usually monarticular, including "dry joint" or from aseptic inflammation associated with other systemic conditions.

Gonorrhoeal arthritis is usually ushered in as an acute process. Either the synovial membrane is mainly affected or sometimes a bursa and the effusion is intra-articular, or more commonly periarticular structures are the seat of the affection and the effusion is around rather than within the joint. It may become sero-purulent or purulent. Either form tends to become chronic and resistant to treatment. It is mono-articular, the osseous tissues are not involved. The swollen joint is a feature of the clinical picture.

An infectious arthritis in which the invading organism is not specific generally begins more or less acutely and commonly is the sequella of an acute process, the location of which is ordinarily clearly indicated by the clinical history. As an example, the arthritis following tonsillitis may be cited. Any other local infection may serve as well as the source of the infection or toxæmia that underlies the arthritis. In the great majority of instances, it is polyarticular, although some of the joints may be only transiently affected, the arthritis reaching a subacute or chronic stage in a relatively small number of joints. When the original focus is less acute, the arthritic manifestations are correspondingly more gradual in their onset. The process ordinarily involves all the joints to be affected in a comparatively short time, the tendency of extension to other joints being less than in some other forms of arthritis. The formation of sero-fibrinous exudate, characteristic of infection regardless of location, applies to the form of arthritis under consideration, in consequence of which there is thickening of the fibrous and synovial membranes with formation of adhesions, even to the obliteration of the synovial cavity. If the onset is acute, the adhesions predominate, if chronic with low grade inflammation, the thickening of the membranes is more marked. In certain instances, actual bacterial invasion of the joint may be demonstrated; in others, it has been held that the result is entirely brought about by the action of bacterial toxins. The X-ray affords valuable information in establishing the pathological anatomy more or less characteristic of infectious arthritis.

The organisms isolated include more commonly varieties of the staphylococcus and the streptococcus groups, occasionally the typhoid bacillus, the pneumococcus or even the diphtheria bacillus. Other organisms have also been described, to some of which special names have been ascribed.

Still's disease is a term applied to a form of chronic polyarticular arthritis, generally believed to be infectious, and occurring before the age of fifteen years. Not only are there enlarged joints, but marked glandular involvement, together with enlargement of the spleen, and, as a general rule, marked muscular atrophy and wasting. It should not be confused with non-infectious polyarthritis to which childhood is not immune, but which is

usually not accompanied by the glandular evidences of infection. There is some reason to believe that the condition develops following a more or less general infection, in the course of which the pituitary has become involved and that the subsequent arthritis is associated with the pituitary dysfunction.

The *atrophic* type is a polyarthritis, chronic in onset, and belongs to early and middle adult life, being more frequent in women than men. Neither the onset nor search for bacterial agents suggest an infective origin. It begins in the smaller articulations, particularly of the hands, and extends to the larger joints with varying rapidity in individual cases. It begins by a hypertrophy and round cell infiltration of the normal tissue, elements of the synovial membranes, particularly of the tips of the villi, giving to the surface a velvety appearance with an irregularly roughened nap. After long periods of time, several years, the membrane takes on the characteristics of cicatrization. Shrinkage of the cartilage, even to the production of small areas of erosions, next occurs. Similar lesions in the bone are the last to appear. While this change is in active occurrence, it is claimed that calcium phosphate may be eliminated in double the amount ingested. It is recognized that nervous strain is a frequent occurrence early in these cases and it has been suggested that endocrine abnormalities may be the cause of a metabolic pathology that is responsible for the affection.

*Hypertrophic* arthritis may or may not be polyarticular. It may be general but is quite apt to be emphasized in particular locations, in which event it receives the particular designation suggestive of such location, e. g., *Heberden's nodes*, involving the phalangeal joints, remembering, however, that similar excrescences are sometimes seen in gout or even independently of arthritis of other joints, *morbus corae senilis*, involving the head and neck of the femurs, *spondylitis*, involving the articulation of some regions of the spine, not forgetting that the spine is subject to any of the various forms of arthritis described, etc. Hypertrophic arthritis more frequently attacks the middle-aged and elderly and men rather than women. The articulations involved in the order of frequency are fingers, knees, spine, hip, elbows and feet. Further, involvement of the smaller joints are more common with women and of the larger with men. This may be because occupation and exposure are probable etiologic factors. The synovial structures show very little if any change, the cartilages are irregularly hypertrophic, particularly where adjacent to bone, while hypertrophic changes in the bone, notably lipping, constitute the characteristic findings upon which the diagnosis may be based. Constitutional disturbances play a minor part in the affection. Pain is referable to the mechanical conditions established by

the pathological anatomy. There are no premonitory acute manifestations.

*Chronic villous* arthritis, or "dry joint," most commonly met with in the knee as a result of trauma or flat foot, is not due to any general disease but is purely local, a so-called "static" arthritis. There is crepitation or creaking of the joint on motion with varying degrees of pain and tenderness on movement. Villi may become engaged in the joint so that pain from pinching results. Not infrequently a joint of this description tends to become locked. The suggestion that this may be due to lack of the mucilaginous constituent because of hypothyroidism is interesting though not proven. Attention to this condition, if present, is of course indicated.

In *gout*, there is lacking the general pathology characteristic of the arthritic joints already described. When the case is advanced, with tophi involving the joint, and frequently, as well found elsewhere, as in the ears, there is little likelihood of confusion with other forms of arthritis. In the earlier history, there is considerable similarity during acute exacerbations to the infectious joint, particularly where the lesions are chiefly in the fingers, though capsular thickening is not a feature and portions of the joint remote from the line of articulation are more often concerned. The blood uric acid is relatively high, and when not accompanied by renal involvement constitutes a definite gouty factor. The osseous changes as shown by X-ray, may include destructive or absorptive changes in the shafts of the long bones, highly refractive nodules at the joint which may extend along the shafts of the bones and hyperplastic spurs, limiting motion or even producing ankylosis. The sudden onset, repeated separate attacks, and involvements of meta-tarsophalangeal articulation of the great toe or metacarpophalangeal of the thumb, are clinical features to excite suspicion.

It appears from the foregoing description of the various types of chronic arthritis, that they present a widely varied etiology and pathology. Treatment in general is (1) curative, directed to the restoration of the part to normal structure and function, or (2) palliative, directed to the relief of the effects of dysfunction, including pain. When chronic structure changes are established, surgery may intervene to correct plastic pathology and re-establish function in some instances, but as a rule there is limited or no opportunity to restore normal structure.

Palliative treatment, so far as it has to do with the removal of etiologic factors, is in a sense curative even though it makes no correction of the tissue damages already done. It includes removal or restoration to normal of all foci of infection, for even if infection be not recognized as a causative factor, it may play a secondary part in the production of pain through the action of bacteria or their toxins upon an already estab-

lished pathologic condition. In the case of tubercular, syphilitic, or gonorrhoeal arthritis, specific systemic treatment for these conditions is called for. Thus, the writers have found tuberculin administered in proper increasing dosage, over a long period of time, of very great value, as also the recognized antisyphilitic treatments, and a course of gonorrhoeal vaccine in the corresponding conditions.

With the non-specific cases, whether infectious or not, general systemic treatment is of very great importance. Unfortunately, this is frequently neglected. The sturdy individual may tolerate a certain degree of gastro-intestinal toxæmia, yet the arthritic patient finds in such a condition a constant source of irritation to his pathologic joint, oftentimes greatly exacerbating the local distress and pain by the irritating action of absorbed toxins and their disturbing influence on the nervous balance. A study of the bacterial flora of the bowels often reveals a dominating coccal or other foreign bacterial invasion of the contents that should be corrected by proper medical treatment and dietary regulations, it must be remembered too, even an apparently normal flora may at times give rise to a toxæmia by the excessive absorption of toxins. Unfortunately, the treatment of such conditions is not a simple formula and calls for varied measures suited to the individual case.

In addition to the medical treatment of the gastro-intestinal tract, surgical corrections are at times in order. These frequently include removal of apical foci by tooth extraction, the enucleation of badly infected tonsils, at times the correction of sinus infection, and also, occasionally the correction by overcoming ptosis, kinks, etc., even in extreme cases to the extent of resection of the bowel. Such operations, however, are not to be done as a routine but only when clearly and definitely indicated. The danger of exacerbation from systemic absorption must not be overlooked. It is our experience that a course of treatment with an autogenous vaccine prior to operative procedure, where such is apt to be followed by absorption of infectious material, as for example, in extensive extraction of teeth and in tonsilectomy, does much to prepare the patient for the shock of this treatment.

Systemically, treatment is to be directed to whatever pathologic condition the individual may present. If he be anemic, the condition is to be treated, if diabetic, not only must the diet be adapted to the loss of sugar utilization, but any complications, such as acidosis, even though mild in degree, must be corrected. Of particular moment is the consideration of the renal excretion. We find the existence of some degree of renal insufficiency of more frequent occurrence than is generally recognized. It is not sufficient to test the urine for albumin and conclude from

its absence that renal function is normal. It is important to compare the volume, specific gravity, chlorides and urea of the urine excreted during the two-hour periods of the day and the 12 hours night, and deduct therefrom the indicated conclusions as to renal function and even occasionally to make use of the phenol-sulphone-phthalein renal function test. Further, the blood chemistry is of value in this direction, particularly as to the uric acid, which may be our first intimation of renal insufficiency, even though the gouty factor of a high blood uric acid be not accompanied by the other factors that combine to make the joint picture that of gout.

In the genito-urinary tract, the existence of a pyelitis, even though simply catarrhal, the presence of a cystitis, either latent or active, the existence of obstruction from prostatic enlargement, any latent or active urethritis, in the female, infections of the vagina, cervix or tubes are all conditions to be determined and if present, corrected, in the relief of the localized joint symptoms presented by the chronic arthritic whose welfare we are considering.

The object sought by the patient in a majority of instances includes the relief from pain, and the treatment accorded for this symptom is an important feature of the handling of these cases. It has already been pointed out that the quality of the blood, as determined by the maintenance of a normal composition and by freedom from infections and their products, as also from undue accumulation of products of metabolic waste, are all factors tending more or less to produce or increase pain, and that its ultimate relief calls for the restoration of blood to normal. This is ordinarily a matter of time, however, and frequently of considerable time and in the interim such relief as is reasonably possible must be accomplished by more direct treatment.

Medical treatment usually constitutes a necessary part in the relief of pain and distress. The use of narcotics is not to be considered. Whatever service, if any, they may be called upon to perform in the pain of acute arthritis does not apply to the subacute and chronic joint pain, for here the danger of habituating the patient removes entirely any justification for their employment. Probably no class of drugs is so generally applicable as the salicylates. Just how they act is still not entirely clear. That they may reduce any intestinal toxæmia and that they may lower a pathological blood uric acid are undoubtedly true. That they possess a general analgesic action probably is equally certain, thereby affording relief not only at the joints proper, but to the muscles that ache from the strain resulting from the abnormal functioning of the joints. A more or less serious obstacle to their use is that they are not always well-tolerated by the stomach and usually are not for any prolonged period of

time On this account, the form of administration is a matter of moment While acetyl-salicylate (aspirin) is less open to this objection, a considerable experience with the various forms has led us to prefer the combination as the ethyl-salicylate in 5 minim capsules under the trade name Sal-ethyl, since this is less liable to produce toxic side effects and appears to have an equal or even greater efficiency The usual dosage is 10 to 20 minims three times a day

Where a high blood uric acid is a prominent factor, there are theoretical grounds for the administration of *phenyl-mcnchonnac acid*, sold under various proprietary names, such as Atophan For a brief period, say ten days, it has been shown that full doses of this drug do reduce strikingly the blood uric acid If it is employed for this purpose, the salicylate treatment should be employed during alternate ten days The drug does not have the general analgesic action of the salicylates, for which reason it does not give the same relief from pain and so is ordinarily not accounted as efficient by the patient Notwithstanding this, its employment in true gout is certainly indicated The dose of  $7\frac{1}{2}$  grains should be accompanied by 10 to 20 grains of sodium bicarbonate

The use of iodides is a time honored treatment They have no analgesic action, but they do, particularly the potassium salt, have the effect of a saline diuretic and so may to some extent indirectly relieve pain by promoting renal elimination of metabolic waste products At the same time it must be realized that they exert an irritating action on the kidneys and frequently on that account are contra-indicated Further, in cases of hypothyroidism, where this contributes to the systemic condition, the iodides tend to restore to normal the thyroid activity The danger of overstimulating this activity is alleged, but the writers have not experienced this in their use Finally, the chief claim for the iodides is their promotion of absorption of exudates and fibrous tissues involving the chronic

joint, similar to such absorption of gummatous formations in syphilis It is difficult to demonstrate whether or not they do accomplish this result, but they continue to be used and for this purpose rather than for any immediate relief of pain

In some instances *local treatment* constitutes an important part in the relief of pain, although in others it plays little or no part As is to be expected, the chronic joint is less responsive than the acute or the acute exacerbation of the chronic Rest, often, accomplished by fixation, is of first importance Fixation may be secured by application of the splint, cast, or iron brace, according to the individual case The hydrotherapeutic application of hot and cold is of value where stimulation of the joint tissues is desired The well-tried procedure of alternately applying hot water for five minutes and cold for ten, either as a spray, lavage, or with towels, accomplishes this end Other physiotherapeutic measures of greater or less efficiency include massage, heat (baking), diathermy, heliotherapy, high rectal irrigation, and electric massage Their efficiency is probably overrated in many instances and their effects, when any, are transient, although occasionally they do give comfort that persists for a time In obstinate cases they naturally will be tried The local use of methyl salicylate or oil of gaultheria, so extensively practiced, likewise comes under this head Whether its action is that of an anodyne, counter irritant, or from absorption, it plays only a minor part in relief from pain in chronic arthritis

## THE POLICY OF THE NEW YORK STATE LABOR DEPARTMENT'S DIVISION OF INDUSTRIAL HYGIENE\*

By LELAND E COFER, M D,

NEW YORK CITY

I AM very grateful for the privilege of appearing before you today and I wish now to acknowledge with thanks the kindness of Dr Orrin Sage Wightman, the President of the New York State Medical Society

Before going into the matter of the policy of the Industrial Hygiene Division of the New York

State Department of Labor, I will say a word about the division itself and its functions

As a result of the interest and endeavor of the Industrial Commissioner, Honorable Bernard L Shientag, the division received an increased appropriation effective July 1, 1923, and in consequence the personnel has been increased and its scope of activities broadened

Besides a director the division now has avail-

\*Read at the Annual Meeting of the Medical Society of the State of New York, at New York City, May 22 1923

able specialists in industrial disease research, expert medical inspectors of factories, chemical engineers, mechanical engineers, chemists, expert lay factors inspectors and expert lay accident inspectors. In addition it has lately opened an industrial hygiene clinic under the joint auspices of the Reconstruction Hospital, in New York City, the College of Physicians and Surgeons, and the Division of Industrial Hygiene. The division itself has also been reorganized and is now being conducted under four heads or sections

First—Section of Expert Inspection

Second—Section of Special Research

Third—Section of Accident Prevention

Fourth—Section of Education

The Section of Expert Inspection gives expert assistance to the Bureau of Research and Codes of the Labor Department in matters relating to the character and design of the various devices for removing noxious fumes and dusts from workrooms, and also gives assistance relative to accident prevention devices. It also gives assistance on projects concerning the heating, lighting and ventilation of factory buildings.

In addition, it renders advice as to the physical condition of workers in plants or factories where conditions are alleged to be unfavorable from the standpoint of industrial hygiene standards. This includes special physical examinations where expert opinion is necessary to determine whether a special process or substance is detrimental to health.

The Section of Special Research conducts studies into the character of the diseases caused by or associated with industry, for example. It is investigating the effect of high temperatures and high humidities upon workers as in the laundry industry, also the effect of carbon monoxide upon workers who are exposed to air constantly contaminated by this gas.

It follows up by special inquiry new problems as they are met with, for example. It is investigating the probability of supplementing the mechanical methods of removing noxious fumes and gases from workrooms by chemical means. It is also holding a survey to determine the effect of industry upon children.

The Section of Accident Prevention is engaged in constantly dispatching expert accident inspectors to the scene of recent accidents, both to get a record as to the cause, details and salient point of the accident from which to find a moral, and also to advise with the employer, shop foreman and workers as to the necessary course to pursue in order to prevent further accidents of a similar nature.

The Section of Education, as its name implies, aims to disseminate where it will do the most good, knowledge concerning the hygiene of industry and the prevention of accidents. This is ac-

complished by radio talks, moving pictures, lectures, pamphlets for distribution and contributions to the magazines and newspapers.

The problem is to ascertain to what extent our knowledge of the nature, cause, prevention and treatment of the diseases caused by industry is applied in this State and to what extent the application is effective. This information will not only demonstrate what existing preventive measures are obsolete or unnecessary, but it will also indicate the necessity or not for new or additional measures. If this information can be obtained it can be used as a guide in framing new legislation, either protective or administrative.

The problem, as I see it, can only be solved by a policy of co-operation between the medical profession of our State, the State and Municipal Public Health organizations and the Industrial Hygiene Division of the State Department of Labor. This division stands ready to aid the medical practitioner in solving the disease problems in industry in order to conserve the usefulness if not the life of the worker and incidentally the interest of the employer. Let it be understood here that the Division of Industrial Hygiene does not treat patients. It acts as an intermediary on medical and hygienic matters between the State on the one hand and the worker and the employer on the other and it is now seeking the aid of the medical profession for the purpose of enlarging as far as possible the scope and effectiveness of this work. After all, who, in the long run, is likely to come into as intimate contact with the worker as the physician? We may study the literature and read papers to each other as much as we please to increase our knowledge of industrial diseases, but the two things most needed just now, let me repeat, are familiarity and interest in industrial hygiene on the part of the medical profession in our State.

While the State law requires the reporting of certain diseases and poisonings which are compensable, there are a number of diseases which are compensable but not reportable, also many poisonings and diseases directly tracable to occupation but which are neither reportable nor compensable.

At present the Division of Industrial Hygiene has knowledge only of the cases reported under Section 206 of the State Labor Law, unless occasionally some case is referred by the Compensation Bureau for attention or investigation.

Art 7, Sec 206 *Physicians' Reports of Industrial Poisonings*. Every physician attending any person whom he believes to be suffering from poisoning by lead, phosphorus, arsenic, brass, wood alcohol, mercury or other compounds, or from anthrax, or compressed air illness, contracted as the result of the nature of such person's employment, shall send to the Commissioner a report stating the name and address and place

of employment of such person and disease from which he is suffering, with such further information as may be required by the Commissioner

The results of this law in yielding data as to the number and kind of diseases caused by industry year by year in this State are as follows

For the eleven years ending with 1923 the total cases reported were 1,485 with 124 deaths, or an average of 135 cases and 11.4 deaths each year, this in a state with a total population in 1920 of 10,384,144, and an industrial population of 1,300,000

Now compare these figures with the showing made in Ohio for the fiscal year ending June 30, 1922, when 756 cases were reported out of the total population of 5,759,368. In other words, if Ohio with a total population of 5,759,368 yields 756 cases of industrial disease yearly, New York with her total population of 10,384,144 should yield, not 135 cases, but approximately 1,500 cases

As a result of an inquiry made of 10,200 physicians in this State by the Division of Industrial Hygiene of the New York State Department of

Labor as to the number of diseases caused by industry which each physician had treated during the calendar year of 1923 replies were received from 3,000 physicians, who reported a total of 217 cases of industrial disease. Now, if 3,000 physicians in New York State report 217 cases, how many should 10,200 physicians report? In Ohio in one year 178 cases of lead poisoning were reported, in New York State, 65 cases, where approximately 10,000 persons are exposed to lead poisoning in fully 150 different trades

The policy of the Industrial Hygiene Division stated concisely, is as follows

1 To develop and function on strictly scientific lines and in co-operation with the medical profession of the State, and not to use police methods if it can be avoided

2 To endeavor to stimulate interest in the early recognition of industrial diseases and use this advance information to correct the causes at the source

3 To study industrial diseases with a view to the awarding of compensation on a basis equally fair to the employer and employee.

## LICENSING CHIROPRACTORS

At the recent hearing on proposed Medical Practice bills before the joint committee on Public Health of the Senate and Assembly, several questions were asked which set us thinking

"Why don't the physicians come to an agreement with chiropractors in regard to giving chiropractors licenses to practice?"

We would answer Because chiropractors disagree among themselves as to what chiropractic is

The chiropractors themselves publicly reiterate in print that they are divided into two major antagonistic groups, each condemning and repudiating the other

The original major group is led by B. J. Pal-

mer, son of the founder of chiropractic, who runs a chiropractic school in Davenport, Iowa. He and his followers claim that chiropractic means the detection of pressures on nerves at their exit from the spinal column, and the removal of the pressure by manipulation of the bones of the spinal column. He pretends to teach how to detect pressures by means of the sense of touch, the spinograph (which is the X-ray), and an instrument called the neurocalometer

If by chiropractic is meant the system that is taught and practiced by B. J. Palmer, then physicians will have nothing to do with it and will not for a moment consider entering into any agreement with a chiropractor

of employment of such person and disease from which he is suffering, with such further information as may be required by the Commissioner

The results of this law in yielding data as to the number and kind of diseases caused by industry year by year in this State are as follows

For the eleven years ending with 1923 the total cases reported were 1,485 with 124 deaths, or an average of 135 cases and 11.4 deaths each year, this in a state with a total population in 1920 of 10,384,144, and an industrial population of 1,300,000

Now compare these figures with the showing made in Ohio for the fiscal year ending June 30, 1922, when 756 cases were reported out of the total population of 5,759,368. In other words, if Ohio with a total population of 5,759,368 yields 756 cases of industrial disease yearly, New York with her total population of 10,384,144 should yield, not 135 cases, but approximately 1,500 cases

As a result of an inquiry made of 10,200 physicians in this State by the Division of Industrial Hygiene of the New York State Department of

Labor as to the number of diseases caused by industry which each physician had treated during the calendar year of 1923 replies were received from 3,000 physicians, who reported a total of 217 cases of industrial disease. Now, if 3,000 physicians in New York State report 217 cases, how many should 10,200 physicians report? In Ohio in one year 178 cases of lead poisoning were reported, in New York State, 65 cases, where approximately 10,000 persons are exposed to lead poisoning in fully 150 different trades

The policy of the Industrial Hygiene Division stated concisely, is as follows

1 To develop and function on strictly scientific lines and in co-operation with the medical profession of the State, and not to use police methods if it can be avoided

2 To endeavor to stimulate interest in the early recognition of industrial diseases and use this advance information to correct the causes at the source

3 To study industrial diseases with a view to the awarding of compensation on a basis equally fair to the employer and employee

## UNALTERABLY OPPOSED TO SO-CALLED CULT BILLS BEFORE LEGISLATURE

The University of the State of New York  
The State Department of Education  
Albany, N Y,

March 9, 1925

Editor, NEW YORK STATE JOURNAL OF MEDICINE,  
Medical Society, State of New York

MY DEAR SIR To my surprise, a number of the newspapers in reporting the hearing on the amendments to the Medical Practice Act held last Wednesday afternoon in the Assembly Chamber, have stated that I acquiesced in the position taken by a very prominent speaker I want to disclaim any such acquiescence whatsoever and to reiterate what I stated at the hearing, that I am unalterably opposed to every one of the so-called cult bills now before the Legislature, and am, as well, everlastingly contending for the principle that no one shall be licensed to practice any phase of medicine in this State unless he shall meet the educational requirements now prescribed in the present medical practice act and the rules of the Board of Regents of the University of the State of New York.

It is true that I stated that Senator Fearon's bill is the least objectionable bill, because he concedes every proposition laid down in the Karle-Dunmore bill, but while conceding everything that we ask, his bill proposes to license under a waiver clause a certain number, a comparatively small number it is true, of men who have been practicing chiropractic in this State for eight years As I stated to him, even though the

number so admitted be small, it violates the fundamental principle for which this Department is contending, namely, that there shall be no lowering of the standards for licensing any one or any number of ones who want to practice upon the sick or afflicted

At the hearing I agreed to accept the amendments, as follows

1 That which will protect the internes to be employed in the State hospitals

2 The omission of the phrase "Sundays and legal holidays," thus giving to those in prison jail liberty on these days

3 The reinsertion of that which was omitted and which relates to contraception

4 The omission from the penalties of that sentence which provides that the provisions of the debtor and creditor law and Section 72 of the civil rights law should not apply

I also agreed to the inclusion of optometry with chiropody, dentistry and veterinary medicine, providing those practicing are legally authorized and licensed under the laws of this State so to do

With these exceptions, the Karle-Dunmore bill stands exactly as it was introduced originally and will so stand I shall not yield any further amendments to this bill, win or lose

Very respectfully yours,

(Signed) AUGUSTUS S DOWNING,  
Assistant Commissioner and Director  
of Professional Education

---

## THE ANNUAL MEETING

Physicians are already beginning to ask about the details of the Annual Meeting of the Medical Society of the State of New York, to be held on Monday, Tuesday, Wednesday, and Thursday, May 11 to 14, 1925, in Syracuse, N Y The arrangements for the various features of the meeting are in the hands of active committees and are being worked out as rapidly as possible Dr Frederick H Flaherty, of Syracuse, and his colleagues on the Committee of Arrangements have mapped out the general arrangements already, although the meeting is nine weeks in the future

The two principal features of the meeting will be the sessions of the House of Delegates and the scientific meetings A third major feature will be added this year—a complete tuberculosis exhibit and demonstration, lasting all day Thursday

There will be many minor features which in a smaller society would be classed as major There will be a stated annual meeting which will be

open to the public One evening will be given over to the annual dinner A conference of the secretaries of the County Societies is planned

The tuberculosis program for Thursday will consist of exhibits, demonstrations and lectures It is planned to bring together a comprehensive exhibit which will illustrate all phases of tuberculosis within New York State Exhibits are promised from the Departments of Health of the State and larger cities, and from the greater lay organizations and sanatoriums which are doing anti-tuberculosis work While the details are not entirely worked out, we are assured that every phase of tuberculosis work will be covered in an interesting way We are especially emphasizing the word *interesting*, because the control of tuberculosis is a goal which is in sight, and its accomplishment depends on the co-operation of the family physicians of the State

There will be a number of meetings of organizations allied to the State Medical Society, notices of which will be printed when they are received

F O

The members of the second major group of chiropractors believe that nerve pressure is not the only cause of sickness, that the manipulation of the back bone is only one among many major means for the cure of diseases, and they therefore practice massage, heat therapy, or any other form of treatment which they think best. Those who belong to the second major group of chiropractors ridicule B. J. Palmer and his narrow views and extravagant claims, and repudiate him to almost as great a degree as physicians do. They are opposed to the recognition of the graduates of the School of B. J. Palmer.

Physicians may consistently agree with the second group of chiropractors in opposing the recognition of the first group.

The second major group of chiropractors is divided into at least two sub-groups who differ in regard to the amount and kind of scientific knowledge that should be required from practitioners. The members of the most advanced sub-group profess to advocate the scientific education of chiropractors to the same degree that

physicians are educated in the preliminary subjects of anatomy, physiology, chemistry, bacteriology, pathology and diagnosis, and they would compel a candidate for a chiropractic license to pass the present Regents' examinations in these subjects.

The other sub-group of chiropractors is composed of those who advocate lesser degrees of training in scientific subjects down to no training at all.

The only chiropractor with whom physicians could come to any sort of an agreement are those belonging to sub-group one, who advocate the present Regents' standards in examination for licenses to practice.

Physicians do not believe that any chiropractors now possess these qualifications except possibly a few graduates in medicine who may have taken a chiropractic course, and therefore physicians cannot enter into any agreement with any large group of chiropractors who are now in practice.

F O

## WAIVERS IN THE MEDICAL PRACTICE ACT

If a cultist is going to practice only one therapeutic procedure, should he be required to study those methods which he will never use? In other words, should he be exempted from the Regents' examinations in such subjects as drugs, surgery and obstetrics?

Can a practitioner of chiropractic or any other drugless therapy or single view cult treat common diseases and conditions of the human body and ignore drugs?

We presume that the word *drugs* includes any liquid or chemical substance which is put on or into the body in order to be taken up by the blood or flesh.

The science of chemistry shows that there are certain substances which positively poison the body, and for which the only remedy is another substance which will counteract the poison, either physiologically or chemically, or both, as for example, bichloride of mercury.

The practitioners of drugless cults wish to be exempt from the study of toxicology, sepsis, serums, vaccines, and endocrines. Can any practitioner ignore these subjects and yet give intelligent treatment in the common run of cases which come to him?

How can any one diagnose diseases without the knowledge of drugs or surgery? Chemicals are introduced into the body for the purpose of testing the kidneys and other organs, and serums are now used for the detection and cure of certain diseases, such as scarlet fever, and of im-

munity, as for example, diphtheria. Surgery is used for taking blood specimens for examinations, for doing spinal punctures, and for detecting collections of fluids in the body. All these procedures are necessary for the detection of common diseases, and every medical student is taught them early in his course. Yet practitioners of drugless therapy claim that they will have no use for the knowledge of drugs and surgery. Physicians have need of both drugs and surgery in *diagnosing* as well as *treating* diseases. Does a drugless practitioner have some occult insight which is denied to physicians? Can the State afford to allow a drugless practitioner to make claims of powers that he does not possess, according to his own confession?

If a practitioner knows a little or nothing about drugs and simple surgical proceedings, he is limited to the methods of the practice of medicine which existed a century ago before anyone dreamed of modern procedures.

The medical profession adheres to its reiterated attitude that no one should be allowed to practice the healing art unless he shall first prove to a competent court that he is familiar with scientific methods and procedures which are in common use in the detection and treatment of diseases. As soon as the practitioner of a cult proves his attainments in science, he ceases to be a narrow cultist and is accepted as a competent chemist, or bacteriologist, or other expert in science.

J N V V

practicers to treat diphtheria and other infectious diseases according to their method, if they desire, but is there any sane man in the legislature today who would vote for such a change in our entire public health system? The legislators would like to get rid of the chiropractors who have pestered them year after year with demand for license, but they should not, for their own comfort license such to treat communicable disease, for by so doing the cost of legislators' comfort will be paid in priceless human lives

From the patience shown by the members of the Public Health Committee at the hearing, it

is difficult to believe that that important Committee of the Senate and the Assembly, that has a peculiar obligation to the health of the public, will allow themselves to be freed from the annoyance of chiropractic lobbying by passing a chiropractic bill that will give licenses without test and that will permit the treatment of communicable disease by unscientific methods

The medical profession must not weary of this fight—the cause is worthy of continued and sustained effort and now, in the closing days of the session let no vigilance relax or effort lag!

---

### LACERATION OF THE WRIST WITH RESULTANT CELLULITIS.

In this action the plaintiff claimed that he had sustained injuries to his right wrist by striking the same against a broken pane of glass, causing a cut and severing one of the main nerves and arteries of the wrist, that the defendant was engaged to treat and care for the injury, that he was so negligent and careless in his undertaking that as a result an infection set in which continued for several weeks and during which time the plaintiff suffered excruciating pain, that the defendant permitted the infection to continue without removing the pus and other matter which gathered in the injury, that the plaintiff finally consulted another physician in an adjoining city who performed an operation upon the plaintiff's wrist, but it is claimed that as a result of the defendant's mistreatment and negligence the injury to the plaintiff had progressed to such an extent that it was impossible entirely to cure the plaintiff's injury and that he was left with a permanently injured wrist, stiffness and loss of function in his hand and fingers

From the facts it appears that the defendant a physician, at about 9 30 in the evening was called on an emergency case and found the plaintiff with a deep laceration of his wrist received by having thrust his hand through a pane of glass while intoxicated and when seen the plaintiff was still in a state of drunken delirium unruly and profane and in a filthy condition. A companion of the drunken man had attempted

first aid measures by applying a tourniquet or rope, which the doctor found on the patient's arm upon arrival. It was necessary for the defendant to call another physician to his assistance as the plaintiff and his companion in their drunken condition could not be physically coped with. The defendant then took the necessary antiseptic precautions, sewed up the wound and applied moist bichloride dressings. On the following day he removed some of the sutures and found the condition satisfactory. Several days later the arm became swollen and the defendant called a physician in consultation who decided there was no necessity for changing the treatment at that time and recommended the continuance of the moist bichloride dressings. Later, upon complaint of pain from the patient and swelling of the arm, a surgeon in an adjacent city was consulted. After this the defendant rendered no further treatment or care to the plaintiff. The surgeon who treated and operated upon the plaintiff found that he had suffered from a vicious infection tending toward a deep cellulitis and that the treatment of the defendant physician was in no way responsible for the claimed bad result and that the same were merely the inevitable results of the plaintiff's original injury. After this action had been pending for some time the plaintiff consented to a discontinuance.

# LEGAL

By GEORGE W. WHITESIDE, Esq  
Counsel, Medical Society of the State of New York

## HEARING BEFORE JOINT COMMITTEE ON PUBLIC HEALTH—SENATE AND ASSEMBLY

The chiropractors were the chief objectors present on the 4th of March at the hearing before the Joint Committee on Public Health of the Senate and Assembly, when the Karle-Dunmore Medical Practice bill was being discussed. As bills are introduced for improving machinery for prosecuting unlicensed practitioners and making more certain the discovery of their offenses and more stringent the punishment, large numbers of chiropractors assemble in the assembly chamber and become a militant and noisy opposition. They appear to be satisfied with the present Medical Practice Act as it has been so ineffective in preventing their unlawful practice.

The best argument in favor of the Karle-Dunmore bill was the array of the opposition who fear its penalties. The New York Chiropractic Society, through its attorney, has no objection to the passage of the bill, provided chiropractors are specifically exempted from its penalties. Their position has always been as seekers of special privilege, who have never attempted to meet the standards required for a license to practice healing and who wish the rights and benefits that belong only to those who have earned them. The same noisy gallery that voiced its opposition to the Medical Practice Act vociferously applauded the supporters of the various chiropractic and drugless methods bills. While Senator Fearon in his chiropractic bill seeks to establish reasonably high standards for future licensing of chiropractors, he, nevertheless, seeks to license chiropractors without examination who have practiced for eight years in this state and are graduates of chiropractic schools or colleges, and those chiropractors who are veterans of the World War he proposes should be licensed without such eight years previous practice. It was stated at the hearing that this would admit from 180 to 200 chiropractors without license. There is not one of these who are to be so specially favored whose qualifications to practice are known or proved. Of this number there may be some reasonably intelligent and some woefully ignorant, some who are sincere and some who are the worst type of charlatan, some who are straight and some who are crooked. But Senator Fearon's waiver clause will not discriminate and weed out the fit from the unfit—it will license all of that class irrespective of their fitness, irrespective of their qualification and notwithstanding their previous conduct.

The Medical Society of the state as an organization made up of men who are licensed by the state, who have met every requirement as to qualification that has been imposed by the state, who stand for high educational qualifications to practice the healing art, can never compromise with anybody or any legislative or executive department on this fundamental proposition. There are no practical or political considerations that should dissuade the profession from this opposition. Banks are required to meet certain specifications before they are permitted to operate under the Banking Law, insurance companies must be organized according to the provisions of law and subject to strict executive supervision. Would any legislator seriously consider passing a bill by which banks and insurance companies that had openly flouted the law and had not met the standards or requirements necessary to receive a charter to conduct the banking or insurance business should receive such a charter by legislative act waiving the requirements of the general law applying to those engaged in these businesses, on the ground that it was a practical or political expedient? There is no practical or political expediency that justifies excusing any class in a community or any individual of the state who seeks a license to practice medicine, whether it be by drugless or other methods, from meeting the educational standards necessary to prove the qualifications of the applicant.

If the State of New York desires to license chiropractors and establish a real test of their fitness as a condition of granting a license, it doubtless has power so to do, but the State must make sure that those who seek to treat disease according to the tenets of this particular cult are sufficiently qualified to diagnose disease before they undertake treatment, and further, must make sure that communicable disease, which is a serious hazard to the public if not treated by scientific principles, shall be treated only by the application of approved scientific treatment.

In the closing hours of the hearing, near mid night, the chiropractor leaders declared their right to treat diphtheria without the use of anti toxin but by their method of adjustment. They declared their rights similarly to treat all communicable diseases which have yielded to present methods based on scientific principles. The State of New York has a right to discard science in the treatment of disease and to license the chiro-

## SUMMARY OF BILLS INTRODUCED IN LEGISLATURE IN SENATE

### Prohibition Enforcement

Senate Int No 29 (conc Assembly Int 527)  
—No further comment

### Commission on Crippled Children

Senate Int No 114 (conc. Assembly Int 226)  
—Passed both Houses, now before Governor

### The Narcotic Bill

Senate Int No 115 (conc Assembly Int 215)  
*Comment* Hearing on this bill to be held on Wednesday, March 11th, before the joint Senate and Assembly Committees on Public Health, at which your Committee on Legislation will appear in favor of the bill

At the conference of County Legislative Chairmen held on Wednesday, March 4th, an affirmative attitude was given on it

**Requiring the Licensing of Private Institutions for the Treatment of Drug Addicts**

Senate Int No 116 (conc Assembly Int 216)  
*Comment* No further comment.

**The State Department of Education Bill Amending The Medical Practice Act**

Senate Int No 211 (conc Assembly Int 307)  
*Comment* At the conference of County Legislative Chairmen but one dissenting vote representing a County Society was heard against this bill

Your Committee on Legislation was instructed to continue to work in behalf of the bill in conjunction with the State Department of Education

The last returns on going to press show that a majority of the delegates of your State Society have voted in favor of the bill

The hearing on this bill was held March 4th before the combined Public Health Committees of the Senate and Assembly, and the following were heard in opposition to the bill

Dr Joseph A Driscoll, representing Kings County Medical Society, which were in opposition to several features of the bill—in general relative to the omission of Section 170-d of the old bill which had to do with the advice against contraceptive measures, second, the supersession of the local District Attorney by the Attorney General at his discretion, being more of a local objection because of the excellent co-operation which the District Attorney gives to the Kings County Medical Society, and lastly, the matter of registration, which is considered unnecessary and uncalled for

Mr H A Bull, an attorney from Buffalo, N Y, spoke in opposition, representing the New York State Drugless Practitioners Society, but dwelt more upon the wish to pass the Gibbs bill, stating that these practitioners were not doctors of medicine, and if the Gibbs bill were adopted and licenses were issued to drugless practitioners, then there would be no serious objection on the part of his Society to the Karle-Dunmore bill, but the terms of the Karle-Dunmore bill were so broad that if it was adopted and the Gibbs bill defeated then they were against it, because the definition of the practice of medicine as it stands today from a lawyers point of view is a joke, being wild in its comprehensiveness. He acknowledged that it included chiropractors in its definition

Mr N B Vanderzee, of Albany, N Y, appeared for the New York State Chiropractic Society with no objection to the bill *provided the lists of exceptions also bore the words "or the practice of chiropractic"* He also made some remarks concerning the doctors regulating themselves

Mr Burton D Esmond, Assemblyman from Saratoga County, then attacked the bill from a legal standpoint, along the lines of the arguments which have been heard before, dwelling constantly upon the animus in the bill

Mr J W Malone, of Brooklyn, N Y, then spoke in opposition on behalf of the Professional Guild of Kings and Queens County, and read as his objections the ten objections published by the Kings County Society in its report of its Legislative Committee

Those who appeared in favor of the bill, by letter or otherwise, were

Frank P Graves, Commissioner of Education, State of New York, and Floyd C Haviland, M D, President State Hospital Commission, who wrote of their inability to be present, but were heartily in favor of the bill,

Owen E Jones, M D, President, Medical Society of the State of New York, who was interrupted by Assemblyman Esmond with a question,

Mary Dunning Rose, M D, representing the Women's Medical Society of the State of New York and the New York City Women's Medical Society, who advanced the arguments by comparative methods as to the necessity of safeguarding the public health as exhibited in the bill,

Matthias Nicoll, Jr, M D, Commissioner of Health, State of New York, then spoke in favor of the bill,

Ralph H Williams, D O, of Rochester, N Y, represented the New York State Osteopathic Society, who was questioned at some length by Assemblymen Berg and Esmond

Mr George W Whiteside, Counsel for the Medical Society of the State of New York, discussed the legal side of the bill and was questioned at some length by Assemblyman Esmond

Jacob Diner, M D, Ph G, Chairman of the Legislative Committee of the New York City Pharmaceutical Association, and former president of the New York State Pharmaceutical Association spoke in favor of the bill

Dr Augustus S Downing, Assistant Commissioner of Education and Director of Professional Education, State of New York, then spoke closing the arguments in favor of the bill, being interrupted by Assemblyman Esmond with a number of questions

An effort will be made to publish the minutes of the hearing, if the Society so desires

**Inspection by State Charities Boards of Children's Institutions**

Senate Int No 228

*Comment* No further comment as yet

### Qualifications of Examiners in Lunacy

Senate Int. No 263

A bill introduced in the Senate by Senator James A Higgins of Kings County, would amend section 61, Insanity Law, relative to qualifications of examiners in lunacy

Referred to General Laws Committees

*Comment* By motion of the County Legislative Chairmen at the conference it was unanimously voted to oppose this bill

### County Public Health Nurses

Senate Int No 283 (conc Assembly Int 399)

*Comment* This bill was also opposed in its present form at the conference of County Legislative Chairmen and it was hoped, as so expressed in the conference, that certain amendments which had been suggested by various members of the State Society would be incorporated in the bill and would be accepted by the introducer of the same in the Senate, Mr Webb, but he has seen fit only to hold the bill up pending the report as coming from the conference of County Legislative Chairmen, but no particular change has yet been made

The bill was introduced by the State Charities Aid Association and it is presumed that the Association is anxious to have it passed in its original form and that this is one of the principal reasons because of which no change has yet been made

### Health Service in Schools

Senate Int No 302 (conc Assembly Int 748)

*Comment* No further comment

### Injured Employee to Select His Physician

Senate Int No 380 (conc Assembly Int. 570)

*Comment* No further comment since at the date of going to press there is a hearing called on this measure for Wednesday March 11, before the joint Senate and Assembly Committees on Labor and Industry

### The Drugless Practitioner Bill (by Gibbs)

Senate Int No 473

*Comment* At the hearing on March 4th, the representatives of this cult appeared before the Public Health Committees and urged the passage of this bill, which it is admitted would allow of the practice of chiropractic and all other cults

It is an omnibus bill covering all phases of anti-medical (so-called) practice, and its proponents claim they are not practicing medicine, but take refuge under the "healing art" term as so used in another of the cult bills

To date no concurrent bill has made its appearance in the Assembly, and it is hoped that the good sense of the legislators will forbid of its being brought out even from committee, though a persistent fight must be maintained against its provisions

### Inspection of School Children

Senate Int No 586 (conc. Assembly Int. 850)

*Comment* Senate bill reported on March 4th, concurrent Assembly bill still in committee

### Free Choice of Physician

Senate Int No 594 (conc Assembly Int 301)

*Comment* See comment on Senate Int 380

### In Relation to Pharmacies

Senate Int No 632 (conc Assembly Int 802)

*Comment* It has been ascertained that this bill has been introduced in the interests of certain commercial groups who would establish so-called drug stores or pharmacies for the outlet of intoxicating liquors

Physicians are unlikely in such an instance to have their prescriptions properly filled in such commercial stores and, therefore, the bill is recalled to your attention in order that we may be recorded as against the same, and thus be assured of proper filling of prescriptions in legitimate pharmacies and drug stores

### Practical Tests of Injured Persons

Senate Int No 647 (conc Assembly Int 184)

*Comment* Hearing on this bill to be held on Wednesday March 11th, at which your Committee on Legislation will be represented to oppose the bill in its present form, in view of the fact that the present verbiage might be so construed legally as to admit of physical examinations being held by incompetent and lay persons

### Physically Handicapped Persons

Senate Int No 671 (conc Assembly Int 868)

*Comment* No further comment

### Abolishing Office of Coroner, Westchester County

Senate Int No 673—Senate bill reported February 18th, February 19th, third reading, February 23rd, passed; February 24th, to Assembly Internal Affairs Committee, March 4th, reported, March 5th, third reading

### Admission of Foreign Practitioners

Senate Int No 693 (conc Assembly Int 950)

*Comment* No further comment

### Revocation of License to Practice Medicine

Senate Int No 701

*Comment* No further comment

### Hospital for Crippled Children at West Haverstraw, N Y

Senate Int No 786 (conc Assembly Int 1074)

*Comment* At the conference of County Legislative Chairmen this bill and the succeeding bill in relation to the State Institute for the Study of Malignant Disease at Buffalo, were considered,

and it was unanimously carried that the legislators be importuned to defer action on these measures for a year, inasmuch as the physicians believe such important questions should not be acted upon without deliberation, in view of Senate Bill Int No 671, which has to do with physically handicapped persons and is in itself a complicated measure which should have a year of trial at least

#### **State Institute for Study of Malignant Disease**

Senate Int No 787 (conc Assembly Int. 973)

*Comment* See comment on Senate Int 786

#### **Rural Hygiene**

Senate Int 716 (conc Assembly Int 969)

*Comment* No further comment

#### **The Bouton Chiropractic Bill**

Senate Int 789—A bill introduced in the Senate by Senator Arthur F Bouton of Roxbury, N Y, would define and regulate the practice of Chiropractic

Referred to Public Health Committee

*Comment* At the Conference of County Legislative Chairmen it was voted unanimously to maintain the position taken heretofore by the Medical Society of the State of New York, that the definition of the practice of medicine is broad enough to include all who would practice the healing art, provided that the requirements of a basic education in the fundamentals were fulfilled, and that he who would practice a certain type of healing had proven to the satisfaction of competent judges in all lines of scientific endeavor that that special type of practice desired to be followed was based on scientific facts of the present day and squared itself with all of the sciences in its various features of application

The Medical Society of the State of New York is opposed to cultism of any type or form which does not recognize these broad fundamentals, and with this declaration your Committee on Legislation and other speakers appeared at the Legislative hearing on March 4th before the joint Senate and Assembly Committees on Public Health and opposed all of the cult bills which have been introduced thus far

At the hearing, the following spoke against these cult bills

Orrin S Wightman, M D, of New York, former President Medical Society of the State of New York

James N Vander Veer, M D, Chairman Committee on Legislation, Medical Society of the State of New York, who was questioned at some length concerning the features of the reasons why the medical profession were so solicitous as to the care of the public health

George R Critchlow, M D, of Buffalo, member of the Committee on Legislation, Medical

Society of the State of New York, dwelt especially upon the scientific advancements in medicine and the prevention and cure of many of the present diseases, which formerly were wide spread He was questioned by Assemblyman Berg and Senator Fearon regarding the latter's bill to which attention is called later in the comments During the course of his argument, he was interrupted by Mr John Nathanson, a drugless practitioner of Buffalo, who wished again to plead the cause of the drugless practitioner

James F Rooney, M D, former President of the Medical Society of the State of New York, then brought out the various waiver clauses in the various cult bills and spoke in opposition to them along the line of education and particularly of training, pointing out that one might cram for an examination, but that in training there enters in the experiences of the preceptor and the contact between student and patient

He drew an analogy between the medical profession and the legal profession and the jealousy with which the legal profession at the present time guards its portals In this he portrayed the reasons why anyone who practices any part of the healing art must be schooled to know the diagnosis as in the cases seen of a pregnant woman or one who has a fibroid tumor of the uterus, as well as why it would be necessary for cultists to recognize and be able to diagnose cases of cancer Also he objected to the admission of cultists of chiropractic type under a waiver clause in the Fearon bill who had practiced for 8 years since having had certain preliminary educational qualifications and supposed experience in practice, they most of all should be able to pass a reasonable examination in fundamentals

Thomas R Thorburn, D O, President of the New York State Osteopathic Society, then read excerpts in his argument, which tended to show that chiropractic was evolved from osteopathy and that if chiropractors really had anything in their system of treatment it was along the lines of osteopathy and should be recognized as such and they should be required to pass an examination equivalent to the present osteopathic examination and closed his argument with the three statements "that the branch of the healing art which is based upon the correction of vertebral subluxations as a cure for disease is already regulated,"

Second, "That the bills under consideration advocate lowering the standards of education for the non-drug practitioners,"

Third, "That it is distinctly class legislation, inasmuch as it extends equal privileges to the chiropractor and osteopath, while requiring a greater professional education of the osteopath"

Dr Thorburn also was questioned at great length, as well as was Dr Downing, relative to the admission of osteopaths in 1907

Matthias Nicoll, Jr, M D, Commissioner of Health, State of New York, closed the arguments against the bills by making statements that chiropractors and other drugless healers, without let or hindrance, were practicing on every kind of case and, speaking from the standpoint of the public health as he viewed it, stated that there were numbers of people who evidently wanted their spines adjusted, their backs rubbed and so forth, and he did not believe it could be stopped by any process of law.

In fact, he had reached the conclusion with sadness and humiliation that while he did not approve of any of the bills that were before them he believed that it was possible for members of the committees on Public Health to get up some kind of a bill that would let in just as few of these people as could be limited, but that as Commissioner of Health he felt that in standing pat the health of the public was suffering through the practices of cultists, who were untrained in matters of health and communicable diseases, and he made the statement that he was against any bill which admitted anyone to practice on any case of any disease listed as communicable in the State or City Departments of Health

Dr Augustus S Downing closed the arguments for the individuals who had spoken against the bill and there ensued a dialogue between Dr Downing and Senator Fearon, relative to the Fearon bill

The Commissioner of Health of the City of New York was represented in opposition to all of the cult bills, except the Fearon bill, if it could be amended to jibe with the lines suggested by Commissioner Nicoll, by Mr O'Sullivan

The hearing adjourned at 7 45 P M and reconvened at 8 55 P M, when the proponents for the various cult bills spoke again in behalf of their bills, the arguments of which were that the scientific men of the present day, as represented in the various sciences making up the practice of medicine, do not understand the practice of chiropractic and drugless healing and,

therefore, examinations, if any, should be given only by members of that cult through legalizing the cult and then in some manner having examining boards

#### Dissecting Material

Senate Int No 851—*Comment* We take up this bill once more and ask County Legislative Chairmen to write in favor of the bill, as it has to do with benefiting laboratories, hospitals and institutions where dissection is carried on for the promotion of scientific investigation

#### Laboratory Supplies

Senate Int. No 943 (conc Assembly Int. 1167) —Bill printed in full in Feb 27th JOURNAL, under Assembly Int No 1167, page 343

*Comment* The Conference of County Legislative Chairmen went on record as opposed to this bill, for many of the reasons as stated in previous issues

#### A Chiropractic Bill by Mr. Fearon

Senate Int No 944

*Comment* See comment of hearing March 4th, under Senate Int No 789

#### Foreign Licenses

Senate Int No 1123 (conc. Assembly Int 1478)

*Comment* No comment will be offered, as this is essentially an educational bill and inserts the privilege of a physician coming from a foreign country on an equality with a physician entering New York state from another state.

#### Censors State Medical Society

Senate Int No 1176 (conc Assembly Int 1348)

*Comment* This bill is one introduced by Senator Karle and Assemblyman Lattin at the request of the Medical Society of the State of New York, and the County Legislative Chairmen are urged to write the members of the Public Health Committees of Senate and Assembly asking that it be advanced rapidly, since it has to do only with the governing body of the State Society

### IN ASSEMBLY

#### Health Service in Schools

Assembly Int 127—*Comment* Since the previous comment on this bill it has been amended by the addition of the word "podiatrist," and recommended to the Assembly Public Education Committee

#### Practical Tests of Injured Persons

Assembly Int No 184 (conc Senate Int 647) —See concurrent Senate Int No 647 for comment

#### The Nicoll Chiropractic Bill

Assembly Int 185—A bill introduced in the Assembly by Assemblyman William Nicoll of

Schnectady County, would define and regulate the practice of Chiropractic

Referred to Public Health Committee

*Comment* See comment under Senate Int 789

#### The Narcotic Bill

Assembly Int No 215 (conc Senate Int 115) —See concurrent Senate Int No 115 for comment

#### Institutions for Addicts

Assembly Int No 216 (conc Senate Int 116) —See concurrent Senate Int No 116 for comment

**Mentally Retarded Children**

Assembly Int 229—A bill introduced in the Assembly by Assemblyman A Spencer Feld of New York County, would add new section 579-a, Education Law, providing for county supervisors to supervise education of children with retarded development

Referred to Public Education Committee

*Comment* No further comment

**Children's Institutions**

Assembly Int No 236 (conc Senate Int 228)  
—See concurrent Senate Int No 228 for comment

**Free Choice of Physician**

Assembly Int No 301 (conc Senate Int 594)  
—See concurrent Senate Int 594 for comment.

**The State Department of Education Bill Amending the Medical Practice Act**

Assembly Int No 307 (conc Senate Int 211)  
—See concurrent Senate Int 211 for comment

**County Public Health Nurses**

Assembly Int No 399 (conc Senate Int 283)  
—See concurrent Senate Int No 283 for comment

**Disclosure of Confidential Communications**

Assembly Int No 422—A bill introduced in the Assembly by Assemblyman Samuel Rosenman of New York County would amend section 352, Civil Practice Act, by providing physicians and nurses may disclose professional information as witnesses in action to annul marriage on ground of fraud

Referred to Codes Committee

*Comment* No further comment

**Prohibition Enforcement**

Assembly Int No 527 (conc Senate Int 29)  
—See concurrent Senate Int No 29 for comment

**Free Choice of Physician**

Assembly Int No 570 (conc Senate Int 380)  
—See concurrent Senate Int No 380 for comment

**Vaccine Virus**

Senate Int No 351 (conc Assembly Int 536)  
—*Comment* Assembly bill reported Feb 19th, Feb 20th, third reading, Feb 26th, passed, Mar 2nd to Senate Public Health Committee

**Chiropractic Bill by Esmond**

Assembly Int No 649—A bill introduced in the Assembly by Assemblyman Burton D Esmond of Saratoga County would amend sections 164, 149, 170, 173, adding new article 8-b Public Health Law, relative to the practice of medicine and to chiropractic

Referred to Public Health Committees

*Comment* See comment under Senate Int No 789

**The Periodic Health Examination of Food Handlers**

Assembly Int No 678—A bill introduced in the Assembly by Assemblyman Harry A. Samberg of Bronx County, would add new section 343-d Public Health Law, requiring that every person employed in preparing or handling of food in any factory or other place shall, at time of entering employment and every six months thereafter, be examined by a physician to determine whether person has a communicable disease

Referred to Public Health Committee

Still in committee.

**Health Service in Schools**

Assembly Int No 748 (conc Senate Int 302)  
—See concurrent Senate Int No 302 for comment

**Medical Inspection in Schools**

Assembly Int No 850 (conc Senate Int 586)  
—See concurrent Senate Int No 586

**Physically Handicapped Persons**

Assembly Int No 868 (conc Senate Int 671)  
—See concurrent Senate 671 for comment

**Regulating Sale of Wood or Methanol Alcohol**

Assembly Int 908—A bill introduced in the Assembly by Assemblyman Frank H Lattin of Orleans County, would add new sections 416, 447, 447-a Penal Law, forbidding sale of wood or methyl alcohol except as methanol, and making it a felony to sell goods or drink or medicinal or toilet preparations for internal use in which there is methanol

Referred to Codes Committee

Feb 23rd, amend and recommit

No further comment

**Reciprocity in Licensure**

Assembly Int No 925—A bill introduced in the Assembly by Assemblyman Edward J Coughlin of Brooklyn, N Y, would amend section 169 Public Health Law, relative to licenses of practice medicine who have received the license in another state

Referrer to Public Health Committee

No further comment

**Rural Hygiene**

Assembly Int No 969 (conc Senate Int 716)  
—See concurrent Senate Int 716

**Admission of Foreign Practitioners**

Assembly Int No 950 (conc Senate Int 693)  
—See concurrent Senate 693

**Dissecting Material**

Assembly Int No 986 (conc Senate Int 681)  
—See concurrent Senate 681

### The Birth Control Bill

Assembly Int No 987—A bill introduced in the Assembly by Assemblyman John Boyle, Jr, of Suffolk County, would amend section 1145, Penal Law, by permitting use of instruments for contraceptive treatment of married persons

Referred to Codes Committee

*Comment* A hearing has been called on this bill for March 17 At the Conference of County Legislative Chairmen a unanimous vote was recorded against the bill

### CENSORS STATE MEDICAL SOCIETY

No 1460

Int 1348

IN ASSEMBLY,

March 2, 1925

Introduced by Mr Lattin—read once and referred to the Committee on Public Health

#### AN ACT

To repeal section three of chapter two hundred and six of the laws of eighteen hundred and eighteen, entitled "An act to amend an act, entitled 'An act to incorporate medical societies for the purpose of regulating the practice of physic and surgery in this state as amended by chapter six hundred and forty-seven of the laws of eighteen hundred and eighty-seven,'" relating to the appointment of censors by the state medical society

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Section three of chapter two hundred and six of the laws of eighteen hundred and eighteen, entitled "An act to amend an act entitled 'An act to incorporate medical societies for the purpose of regulating the practice of physic and surgery in this state'" as repealed in part by chapter six hundred and forty-seven of the laws of eighteen hundred and eighty-seven, is hereby repealed

§ 2 This act shall take effect immediately

For comment, see Senate Int 1176

#### Antivivisection Bill

Assembly Int No 1377—A bill introduced in the Assembly by Assemblyman John L. Buckley of New York City, would amend section 185, Penal Law, by prohibiting scientific experiments on living dogs

Referred to Codes Committee

No 1494

Int 1377

IN ASSEMBLY,

March 3, 1925

Introduced by Mr Buckley—read once and referred to the Committee on Codes

#### AN ACT\*

To amend the penal law, in relation to experiments upon living dogs

*The People of the State of New York, represented in Senate and Assembly do enact as follows*

Section 1 Section one hundred and eighty-

five of the penal law is hereby amended to read as follows

§ 185 Overdriving, torturing and injuring animals, failure to provide proper sustenance A person who overdrives, overloads, tortures or cruelly beats or unjustifiably injures, maims, mutilates or kills any animal, whether wild or tame, and whether belonging to himself or to another, or deprives any animal of necessary sustenance, food or drink, or neglects or refuses to furnish it such sustenance or drink, or causes, procures or permits any animal to be overdriven, overloaded, tortured, cruelly beaten, or unjustifiably injured, maimed, mutilated or killed, or to be deprived of necessary food or drink, or who wilfully sets on foot, instigates, engages in, or in any way furthers any act of cruelty to any animal, or any act tending to produce such cruelty is guilty of a misdemeanor Nothing herein contained shall be construed to prohibit or interfere with any properly conducted scientific experiments or investigations, which experiments shall be performed only under the authority of the faculty of some regularly incorporated medical college or university of this state, *but such experiments or investigations shall not be made upon a living dog*

§ 2 This act shall take effect immediately

*Comment* This is our old friend the Antivivisection bill and County Legislative Chairmen are forewarned that unless they oppose it vigorously to the Codes Committee of the Assembly of which Mr Burton D Esmond is the Chairman, although it has not as yet made its appearance in the Senate but will without doubt do so shortly

#### Practice of Chiropraxy and Podiatry

Assembly Int No 1421—A bill introduced in the Assembly by Assemblyman Morris Weinfeld, of New York County, would add new sections 281-b, 281-c, Public Health Law, making it a misdemeanor to practice chiropraxy and podiatry without a license and providing for revocation of license for certain advertising

Referred to Public Health Committee

No 1538

Int 1421

IN ASSEMBLY,

March 3, 1925

Introduced by Mr Weinfeld—read once and referred to the Committee on Public Health.

#### AN ACT

To amend the public health law, in relation to the practice of chiropraxy and podiatry

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Article thirteen of chapter forty-nine of the laws of nineteen hundred and nine, entitled "An act in relation to the public health,

\* Matter in italics is new matter in brackets [ ] is old law to be omitted.

constituting chapter forty-five of the consolidated laws," is hereby amended by adding thereto two new sections, to follow section two hundred and eighty-one-a, to be sections two hundred and eighty-one-b and two hundred and eighty-one-c, respectively, to read as follows

§ 281-b Unlawful practice of chiropody Any person who shall advertise to practice chiropody, without being lawfully licensed and registered as a chiropodist, or as a duly licensed physician or any business corporation which shall practice chiropody or advertise to practice chiropody, or any person who shall practice or advertise to practice chiropody under a certificate of trade name shall be guilty of a misdemeanor, and shall, on conviction, for each and every offense be punished by a fine of not less than fifty dollars nor more than one hundred dollars or by imprisonment for a term not less than thirty days and not more than one year or by both fine and imprisonment

This section shall not be construed to forbid or prevent the employment by any person, association or corporation of a duly licensed and registered chiropodist to treat employees or members thereof at the expense of said person, association or corporation, nor shall this act apply to any persons or manufacturers who mechanically fit or sell artificial limbs or foot apparatus or appliances

§ 281-c Chiropodist, revocation of license Any licensed and registered chiropodist who shall use, distribute, or display upon any card, sign or advertisement, the words, or any of them, "Foot specialist," "Surgeon," "Orthopedic Specialist," or in any manner upon any card, sign, or advertisement hold himself out as being able to treat all diseases or all ailments or all conditions of the foot, shall be subject to the revocation of his license and the annulment of his registration in the manner provided by section two hundred and eighty-one for proceedings for the revocation of a license and the annulment of a registration

§ 2 This act shall take effect immediately

*Comment* It will be seen by this bill that the chiropodists and podiatrists would raise their standard of ethics and the bill is printed for the information of the medical profession

#### Fearon-Jenks Chiropractic Bill

Assembly Int No 1423 (conc Senate 944)—A bill introduced in the Assembly by Assemblyman Edmund B Jenks, of Broome County, would amend sections 164, 165, 167, 169, 170, 173, 174, repeal section 171, Public Health Law, relative to practice of medicine and to licensing chiropractors

*Comment* See comment under Senate Int No 789

Assembly Int No 1429—A bill introduced in the Assembly by Assemblyman John J Meegan, of Erie County, would amend section 308, renumbers old section 308 as 309 and amends it, Public Health Law, prohibiting sale of eyeglasses and lenses at retail in any store unless a duly licensed physician or qualified certified optometrist is in charge

Referred to Public Health Committee

No 1546

Int 1429

IN ASSEMBLY,

March 3, 1925

Introduced by Mr Meegan—read once and referred to the Committee on Public Health

#### AN ACT\*

To amend the public health law, in relation to sales of spectacles, eye glasses and lenses, as merchandise, at retail

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Chapter forty-nine of the laws of nineteen hundred and nine, entitled "An act in relation to the public health, constituting chapter forty-five of the consolidated laws," is hereby amended by inserting therein, in article fifteen thereof, a new section, to be section three hundred and eight, to read as follows

§ 308 Sales of eye glasses, spectacles and lenses at retail It shall be unlawful for any person, firm or corporation to sell, at retail, as merchandise, in any store or established place of business in the state, any spectacles, eyeglasses or lenses, unless a duly licensed physician or duly qualified optometrist, certified under this article, be in charge of and personal attendance at the booth, counter or place, and each booth, counter or place, where such articles are sold in such store or established place of business The peddling of spectacles, eyeglasses or lenses from house to house or on the streets or highways, by a person other than such an optometrist or physician, also shall be unlawful, notwithstanding any law providing for licensing peddlers

§ 2 Section three hundred and eight of such chapter is hereby renumbered section three hundred and nine and amended to read as follows

§ [308] 309 Construction of article Nothing in this article shall be construed to apply to duly licensed physicians authorized to practice medicine under the laws of the state of New York nor to persons who neither practice nor profess to practice optometry, who sell spectacles, eyeglasses

\* Matter in italics is new matter in brackets [ ] is old law to be omitted

or lenses [either] only on prescription from such physicians or from such duly qualified optometrists [, or as merchandise from permanently located and established places of business]

§ 3 This act shall take effect September first, nineteen hundred and twenty-five

*Comment* This bill is an attempt to protect the public health still further as its text indicates

For the time being there will be no further comment

Assembly Int No 1450—A bill introduced in the Assembly, by Assemblyman Mark T Lambert, of Niagara County, would amend section 196, Public Health Law by providing for registration and licensing of a dental hygienist of a woman fulfilling certain conditions

Referred to Public Health Committee

*Comment* As in the medical profession there are sub-practitioners with the title of "nurse," so in the dental practice are there sub-practitioners with the title of "dental hygienist" and this bill has to do with raising the standard of the latter

The bill is not printed since it does not concern the medical profession to any great degree

#### Laboratory Supplies

Assembly Int No 1167 (conc Senate Int 943)—See concurrent Senate Int 943 for comment

#### Another Esmond Chiropractic Bill

Assembly Int No 1343—A bill introduced in the Assembly, by Assemblyman Burton D Edmond of Saratoga County, would add new article 7-a, amends section 160, Public Health Law, defining practice of the healing art and providing for diagnosis examinations by a State Board

Referred to Public Health Committee

No 1455

Int 1343

IN ASSEMBLY,

March 2, 1925

Introduced by Mr Esmond—read once and referred to the Committee on Public Health

#### AN ACT\*

To amend the public health law, in relation to the practice of the healing art.

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Chapter forty-nine of the laws of nineteen hundred and nine, entitled "An act in relation to the public health, constituting chapter forty-five of the consolidated laws," is hereby amended by inserting therein a new article, to follow article seven, to be article seven-a, to read as follows

\* Matter in italics is new matter in brackets [ ] is old law to be omitted

#### ARTICLE 7-A

#### Practice of the Healing Art

#### Section 146 Definitions

147 Diagnosis examinations

148 Further examinations required to practice any particular branch of the healing art.

149 Construction of this article

§ 146 "Practice of the healing art" is defined as follows a person practices the healing art within the meaning of this chapter who holds himself out as being able to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition, and who shall offer or undertake, by any means or method, to diagnose, treat, operate or prescribe for any human disease, pain, deformity or physical condition

§ 147 Diagnosis examinations No person shall practice the healing art, or any branch thereof, until he shall have passed an examination by the board of diagnosis examiners in the following diagnosis subjects anatomy, physiology, hygiene, sanitation, biological chemistry, diathetics, histology embryology, bacteriology, pathology, diagnosis, and symptomatology The board of diagnosis examiners shall until otherwise provided by law consist of the board of medical examiners Said board shall examine all applicants who present proof of the qualifications required for admission to examination in any branch of the healing art prescribed in this chapter Such examinations shall be uniform in respect to subjects, questions, grading, time and place, papers, values given to answers, method and manner of marking, percentages required for passing, and personnel of board or committee of board, for all branches of the healing art, including physicians and surgeons Each applicant must pass such examination with a rating of at least seventy-five per centum in each subject. Upon passing such examination each applicant must be certified by the board to the regents to have so passed such examination, and the Regents must thereupon credit the same to such applicant upon any further examination of such applicant to practice any particular branch of the healing art as herein defined

§ 148 Further examinations required to practice any particular branch of the healing art No person shall practice any branch of the healing art until he shall have passed the further examination prescribed in this chapter governing admission to practice that particular branch thereof

§ 149 Construction of this article This article shall not be construed to affect commissioned medical officers serving in the United States army, navy or marine hospital service, while so commissioned, nor any one while actually serving

constituting chapter forty-five of the consolidated laws," is hereby amended by adding thereto two new sections, to follow section two hundred and eighty-one-a, to be sections two hundred and eighty-one-b and two hundred and eighty-one-c, respectively, to read as follows

§ 281-b Unlawful practice of chiropody Any person who shall advertise to practice chiropody, without being lawfully licensed and registered as a chiropodist, or as a duly licensed physician or any business corporation which shall practice chiropody or advertise to practice chiropody, or any person who shall practice or advertise to practice chiropody under a certificate of trade name shall be guilty of a misdemeanor, and shall, on conviction, for each and every offense be punished by a fine of not less than fifty dollars nor more than one hundred dollars or by imprisonment for a term not less than thirty days and not more than one year or by both fine and imprisonment

This section shall not be construed to forbid or prevent the employment by any person, association or corporation of a duly licensed and registered chiropodist to treat employees or members thereof at the expense of said person, association or corporation, nor shall this act apply to any persons or manufacturers who mechanically fit or sell artificial limbs or foot apparatus or appliances

§ 281-c. Chiropodist, revocation of license Any licensed and registered chiropodist who shall use, distribute, or display upon any card, sign or advertisement, the words, or any of them, "Foot specialist," "Surgeon," "Orthopedic Specialist," or in any manner upon any card, sign, or advertisement hold himself out as being able to treat all diseases or all ailments or all conditions of the foot, shall be subject to the revocation of his license and the annulment of his registration in the manner provided by section two hundred and eighty-one for proceedings for the revocation of a license and the annulment of a registration

§ 2 This act shall take effect immediately

*Comment* It will be seen by this bill that the chiropodists and podiatrists would raise their standard of ethics and the bill is printed for the information of the medical profession

#### Fearon-Jenks Chiropractic Bill

Assembly Int No 1423 (conc Senate 944)—A bill introduced in the Assembly by Assemblyman Edmund B Jenks, of Broome County, would amend sections 164, 165, 167, 169, 170, 173, 174, repeal section 171, Public Health Law, relative to practice of medicine and to licensing chiropractors

*Comment* See comment under Senate Int No 789

Assembly Int No 1429—A bill introduced in the Assembly by Assemblyman John J Meegan, of Erie County, would amend section 308, renumbers old section 308 as 309 and amends it, Public Health Law, prohibiting sale of eyeglasses and lenses at retail in any store unless a duly licensed physician or qualified certified optometrist is in charge

Referred to Public Health Committee

No 1546

Int 1429

IN ASSEMBLY,

March 3, 1925

Introduced by Mr Meegan—read once and referred to the Committee on Public Health

#### AN ACT\*

To amend the public health law, in relation to sales of spectacles, eye glasses and lenses, as merchandise, at retail

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Chapter forty-nine of the laws of nineteen hundred and nine, entitled "An act in relation to the public health, constituting chapter forty-five of the consolidated laws," is hereby amended by inserting therein, in article fifteen thereof, a new section, to be section three hundred and eight, to read as follows

§ 308 Sales of eye glasses, spectacles and lenses at retail It shall be unlawful for any person, firm or corporation to sell, at retail, as merchandise, in any store or established place of business in the state, any spectacles, eyeglasses or lenses, unless a duly licensed physician or duly qualified optometrist, certified under this article, be in charge of and personal attendance at the booth, counter or place, and each booth, counter or place, where such articles are sold in such store or established place of business The peddling of spectacles, eyeglasses or lenses from house to house or on the streets or highways, by a person other than such an optometrist or physician, also shall be unlawful, notwithstanding any law providing for licensing peddlers

§ 2 Section three hundred and eight of such chapter is hereby renumbered section three hundred and nine and amended to read as follows

§ [308] 309 Construction of article Nothing in this article shall be construed to apply to duly licensed physicians authorized to practice medicine under the laws of the state of New York nor to persons who neither practice nor profess to practice optometry, who sell spectacles, eyeglasses

\* Matter in italics is new matter in brackets [ ] is old law to be omitted.

§ 80 Treatment and care of injured employees The employer shall promptly provide for an injured employee such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. If the employer fail to provide the same, after request by the injured employee such injured employee may do so at the expense of the employer. The employee shall not be entitled to recover any amount expended by him for such treatment or services unless he shall have requested the employer to furnish the same and the employer shall have refused or neglected to do so, or unless the nature of the injury required such treatment and services and the employer or his superintendent or foremen having knowledge of such injury shall have neglected to provide the same, nor shall any claim for medical or surgical treatment be valid and enforceable, as against such employer, unless within twenty days following the first treatment, the physician giving such treatment, furnish to the employer and the industrial commissioner a report of such injury and treatment, on a form prescribed by the industrial commissioner. All fees and other charges for such treatment and services shall be subject to regulation by the commissioner as provided in section twenty-four of this chapter, and shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living.

§ 81 Medical director There shall be a medical director. He shall be a licensed physician in good professional standing, a graduate of a recognized medical college and he shall be appointed by the industrial commissioner from a group of at least three such physicians, proposed by the New York State Medical Society as being qualified for the position. He shall receive an annual salary of eight thousand dollars. It shall be the duty of the medical director to (1) advise the board and the referees on medical questions arising in their work, (2) to examine fee bills and recommend settlements of those in dispute, (3) to supervise and supplement the work of the examining physicians, (4) to put into effect recommendations and decisions approved by the board, (5) to advise with physicians treating compensation cases as to the best methods of treatment and to acquaint them with new developments and trends in the treatment of industrial cases.

§ 82 Examining physicians Examining physicians shall be appointed by the medical director in such number as shall be reasonably necessary for the proper administration of the medical provisions of this chapter. They shall be licensed graduates of recognized medical schools who are in good professional standing. It shall be the

duty of examining physicians to make examinations of injured workers at such time or times as shall be prescribed by the board or the referees or the medical director, to determine the extent and probable duration of disability and the extent of permanent impairment, if any, and such other duties as the medical director may prescribe. Fees of examining physicians shall be recommended by the medical director and determined by the board.

§ 83 Conflicts of medical evidence If, on the hearing of a claim for compensation or for death benefits, a conflict of medical evidence shall arise upon a material issue, the entire record, at the completion of the hearing or hearings, shall be referred to the medical director, who shall nominate a disinterested medical specialist (or, if the medical question involved is not one upon which there is specialization, a disinterested medical authority), to be agreed upon by the parties in interest, to review the testimony, re-open and determine the issues and decide the medical question involved. Such medical specialist or authority may make such physical examination of the claimant as he may deem necessary or proper. The fee of such specialist or authority, when approved by the medical director, as to amount, shall be a proper charge against the insurance carrier or the employer.

§ 2 Section nineteen of such chapter is hereby re-numbered section eighty-four and is transferred from article two to article four-b.

§ 3 Section twelve of such chapter is hereby amended to read as follows:

§ 12 Compensation not allowed for first seven days No compensation shall be allowed for the first seven days of disability, except the benefits provided for in section [thirteen] *eighty* of this chapter, provided, however, that in case the injury results in disability of more than forty-nine days, the compensation shall be allowed from the date of the disability.

§ 4 Section thirteen of such chapter is hereby repealed.

§ 5 This act shall take effect immediately.

*Comment* Attention is especially called to this bill and County Legislative Chairmen and others through County Society action should put their weight behind this bill in asking for its passage.

Especially should members of the Medical Society of the State of New York read over sections 81, 82 and 83, for in these sections Mr. Miller has to a large degree solved the crux of the conflict which has existed in the labor laws relative to medical attendance, judgment, supervision, advice to the industrial board, examination of fee bills, examining physicians, employment of specialists and the like.

without salary or professional fees on the resident medical staff of any legally incorporated hospital *or any one while actually serving as an interne in a state hospital or other state institution in which medical service is provided*, or any person or manufacturer who mechanically fits or sells lenses, artificial eyes, limbs or other apparatus or appliances, or is engaged in the mechanical examination of eyes, for the purpose of constructing or adjusting spectacles, eye glasses and lenses, or any lawfully qualified physician in other states or countries meeting legally registered physicians in this state in consultation, or any physician residing on a border of a neighboring state and duly licensed under the laws thereof to practice medicine therein, whose practice extends into this state, and who does not open an office or appoint a place to meet patients or receive calls within this state, or any physician duly registered in one county called to attend isolated cases in another county, but not residing or habitually practicing therein, or the furnishing of medical assistance in case of emergency, or the domestic administration of family remedies, or the practice of the religious tenets of any church, or any person who shall at the time this act takes effect be licensed to practice any branch of the healing art in the state of New York

§ 2 Section one hundred and sixty of article eight of such chapter as last amended, is hereby amended to read as follows

§ 160 Definitions As used in this article

1 "The education department" means the education department of the state of New York as provided for by the education law

2 "University" means university of the state of New York

3 "Regents" means board of regents of the university of the state of New York

4 "Board" means the board of medical examiners of the state of New York

5 "Medical examiner" means a member of the board of medical examiners of the state of New York

6 "Medical school" means any medical school, college or department of a university, registered by the regents as maintaining a proper medical standard and as legally incorporated

7 The practice of medicine is defined as follows A person practices medicine within the meaning of this article[, except as hereinafter stated,] who holds himself out as being able to diagnose [, treat, operate or] *and prescribe medicine or drugs* for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake [, by any means or method,] to diagnose[, treat, operate or] *and prescribe medicine or drugs* for any human dis-

ease, pain, injury, deformity or physical condition

8 "Physician" means a practitioner of medicine

9 "Surgeon" means one who treats diseases, malformations or deformities of the human body by manual operations or by surgical appliances, other than by the practice of dentistry, registered nurse, chiropody, optometry, midwifery, podiatry, osteopathy, chiropractic, medicine, or other branch of the healing art in this chapter defined

10 Practice of surgery No one but a duly licensed physician shall practice surgery

§ 3 This act shall take effect January first, nineteen hundred and twenty-six

*Comment* See comment under Senate Int No 789

#### Medical Treatment of Injured Employees

Assembly Int No 1351—A bill introduced in the Assembly by Assemblyman Charles P Miller of Genesee County, would add new article 4-b, amends section 12, repeals section 13, Workmen's Compensation Law, relative to medical treatment of injured employees and to procedure Referred to Labor and Industries Committee

No 1463 Int 1351  
IN ASSEMBLY, March 2, 1925

Introduced by Mr C P Miller—read once and referred to the Committee on Labor and Industries

#### AN ACT\*

To amend the workmen's compensation law, in relation to medical procedure.

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Chapter eight hundred and sixteen of the laws of nineteen hundred and thirteen, entitled "An act in relation to assuring compensation for injuries or death of certain employees in the course of their employment, constituting chapter forty-seven of the consolidated laws," as re-enacted by chapter forty-one of the laws of nineteen hundred and fourteen, and further re-enacted and amended by chapter six hundred and fifteen of the laws of nineteen hundred and twenty-two is hereby amended by the insertion therein of a new article, to be article four-b, to read as follows

#### ARTICLE 4-B

##### Medical Procedure

Section 80 Treatment and care of injured employees

81 Medical director

82 Examining physicians

83 Conflicts of medical evidence

84 Physical examination

\* Matter in italics is new matter in brackets [ ] is old law to be omitted.

and fairly mark and grade the answers thereto, all of which shall be done solely for the purpose of determining whether the applicant is reasonably qualified to practice Chiropractic. All applicants reasonably qualified to practice Chiropractic shall be granted a license

**Section 189-g Licenses** All licenses shall be signed by the president and secretary of the Board, and shall be attested by the official seal of the Board. The licensee shall pay to the secretary of the Board before the license is issued a fee of five dollars. Every license to practice Chiropractic shall, before the licensee begins practice thereunder, be registered in a book kept in the clerk's office of the county where such practice is to be carried on, with name, residence, place and date of birth, and source, number and date of license to practice

Every licensee shall be required to pay to the secretary of Board an annual renewal license fee of two dollars

**Section 189-h Licenses Without Examination** Any person of good moral character who has been continuously engaged in the practice of Chiropractic in the state for two years prior to the passage of this article shall be licensed without examination, upon payment to the secretary of the Board of a fee of twenty dollars, if he applies for a license within twenty days after the organization of the Board

**Section 189-i Reciprocity** Any person of good moral character, licensed by a Chiropractic Board of any other state or territory or holding a certificate from the National Board of Chiropractic Examiners, shall be licensed without examination, upon payment to the secretary of the Board of a fee of twenty dollars

**Section 189-j Revocation** Upon complaint to the Board, after twenty days' notice of time and place of trial has been given to any licensee, if it shall be found that he practices anything other than Chiropractic to cure or relieve disease or to remove the cause thereof without having a separate license therefor, or, if it be found that he no longer possesses a good moral character or is addicted to the use of narcotic drugs or in any way is guilty of deception or fraud in the practice of Chiropractic, his license shall be revoked

The action of the Board shall be reviewable by certiorari proceedings

**Section 189-k Finances** Within ten days after the close of every meeting of the Board, the treasurer of the Board shall turn over to the state treasurer all fees and money received by the Board, and take his receipt therefor

The state treasurer shall keep the same in a separate fund, to be used in paying running expenses of the Board and a per diem compensation of fifteen dollars to the members thereof for such time as they may actually spend in the discharge of their official duties and traveling expenses

Payment from such fund shall be made by the state treasurer on the warrant of the comptroller and the vouchers of the president of the Board

If, at the close of any fiscal year, there remains in the hands of the state treasurer from moneys received from the Board, one thousand dollars in excess of all indebtedness of the Board, the same shall be turned over to the public school fund

**Section 189-l Penalties** Any person violating any of the provisions of this article shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished by a fine not to exceed three hundred dollars or by imprisonment for a term not to exceed three months, or by both such fine and imprisonment

**Section 2 Repeal** All acts or parts of acts in conflict with this article, are hereby repealed

**Section 3 When Act to Take Effect** This act shall take effect immediately

*Comment* See comment under Senate Int No 789

This bill is the lowest grade bill thus far introduced

#### **Time for Filing Claims for Personal Injuries**

Assembly Int 1502—A bill introduced in the Assembly by Assemblyman Irwin Steingut of Kings County, would amend section 51, Civil Practice Act, by requiring notice of claim for personal injury to be filed within three months after accident

Referred to Codes Committee

*Comment* Attention of members of the medical profession is called to this bill since it is a general bill which affects all the citizens of this state who carry accident insurance and would limit the legal time for filing of claims in case of accident to three months, wherein some of our accident policies which unlimited time might be changed so as to accord with the shorter time as evidenced in this bill

Comment is simply made because of the fact it is one of the types of legislation that presents itself and affects the individual

It is now put squarely up to the Medical Society of the State of New York to show its good faith in handling the medical situation which has heretofore been so baffling

From all sources there has come a wave of congratulation to Mr Miller for his sound thinking and thus his attempt to place the burden of the medical features of the board squarely where they belong

Letters should be sent to Mr Miller personally, and to the Committee on Labor and Industry as well as to the individual legislators asking for this type of legislation

Assembly Int 1463—A bill introduced in the Assembly, by Assemblyman Richard J Bolton, of Warren County, would add new article 8-b, Public Health Law, creating board of chiropractic examiners and regulating practice of chiropractic

Referred to Ways and Means Committee

Int No 1463

IN ASSEMBLY,

AN ACT

Introduced by Mr Bolton—To amend the Public Health Law creating a Board of Chiropractic Examiners and regulating the practice of Chiropractic and prohibiting the practice of any other mode or system under the name of Chiropractic.

Section 1 Chapter forty-nine of the laws of nineteen hundred and nine, entitled "An act in relation to the public health, constituting chapter forty-five of the consolidated laws," is hereby amended by inserting therein a new article, to follow article eight-a, to be article eight-b, to read as follows

#### ARTICLE 8-B

Section 189 Creation of a Board There is hereby created a Board of Chiropractic Examiners, to be known as the State Board of Chiropractic Examiners

The Board of Chiropractic Examiners shall consist of three members who shall be appointed by the Governor within thirty days after this article takes effect

The appointees shall meet within ten days after their appointment and organize by electing a president, secretary and treasurer, and adopting reasonable rules and regulations for the transaction of business

The appointees shall have the qualifications set forth in Section 189-h of this article Subsequent appointees shall be graduates of Chiropractic Schools or Colleges giving a course of at least three years of six months each, in anatomy, physiology, symptomatology, hygiene, sanitation, Chiropractic analysis and the principles and practice of Chiropractic and requiring actual attend-

ance upon the classes No one may be appointed who practices anything but Chiropractic, as hereinafter defined

The term of office of the first member shall be one year, the second, two years, the third, three years Appointees after the first shall serve for three years, and until their successors shall have been duly appointed and qualified Vacancies shall be filled by the Governor within thirty days

Section 189-a Meetings The Board shall hold regular meetings to examine applicants and the transaction of business, commencing on the first Mondays of March, August, and November in each year Special meetings may be called by the president and secretary upon thirty days notice printed in a newspaper of general circulation in the State

Section 189-b Officers The superintendent of public buildings shall, at the request of the Board, provide an office where meetings may be held Special meetings may be called anywhere in the State

Section 189-c. Eligibility Any person of good moral character, who is a graduate of a Chiropractic School or College teaching Chiropractic, and giving a course of at least three years of six months each in the subjects enumerated in Section 189, and requiring actual attendance upon the classes, shall be eligible to examination, provided he possesses preliminary education or experience equivalent to a high school education, and provided further, that he practices nothing but Chiropractic, as hereinafter defined

Section 189-d Chiropractic Defined Chiropractic is defined to be the science of palpating and adjusting the articulations of the human spinal column by hand only This definition is inclusive and any and all other methods are hereby declared not to be Chiropractic

Section 189-e Practitioners No person shall practice Chiropractic without a license, which license shall not entitle him to practice anything else And, no one may hold himself out as a chiropractor without having a license

Section 189-f Examinations Anyone desiring an examination, shall, at least fifteen days prior to the meeting of the Board, make written application to the secretary Such application shall be accompanied by an examination fee of fifteen dollars The application shall state the name, age, sex, and place of residence of the applicant, the name and location of the school or college from which he graduated, the length of time devoted to the study of Chiropractic, the date of graduation, together with such other data as the applicant may desire to give In case an applicant fails in the first examination, he shall be entitled to a second one, without further fee Application shall be signed and sworn to by the applicant

The Board shall prepare reasonable questions,

is entitled to license. This provision alone is sufficient to condemn the bill.

*In Assembly by Mr Esmond, Int No 649*—This bill seeks to exempt chiropractors from the Medical Practice Act as proposed for amendment under the Karle-Dunmore bills and adds a new article for the licensing of chiropractors. The regents are required, under this bill, to *appoint examiners from the members of the New York Chiropractic Society*, irrespective of their educational qualifications, so that virtually the New York Chiropractic Society is made the licensing power. None of the schools or colleges from which members of such society hold diplomas are recognized by the regents, nor have their standards been the subject of any approval by the regents. So that the Chiropractic Society practically prepares and grades the examination papers to be submitted to applicants for license.

The bill contains, likewise, a provision for exempting from examination chiropractors who have practiced in this state for various periods specified, who are graduates of such chiropractic schools, irrespective of the standard set by such schools or the previous educational qualification of such graduate. None of such schools are under the jurisdiction of the regents. Their standards are not recognized by the regents. Under this bill, upwards of a thousand chiropractors would be licensed without any test of fitness and certified to as qualified without the authorities having any basis for such certification. The educational standards set for licenses in the future have only the effect of benefiting those receiving licenses without examination, by restricting the number that thereafter might be licensed. Chiropractors licensed in other states under a waiver clause, provided their bill is similar to the proposed bill, would be licensed in this state.

*By Mr Fearon, Senate Int No 944*—This bill is somewhat like Assemblyman Esmond's bill, in that it is ingrafted upon the Karle-Dunmore Medical Practice Act, which specifically exempts from the operation of that act chiropractors and provides for licensing chiropractors after examination, but permits a thousand or more to be licensed without examination. Chiropractors who have been practicing in this state for eight years and who are graduates of chiropractic schools, irrespective of the time they spent in study at such schools, or the standards of such schools, or the previous educational qualifications of such graduates. Those who cannot qualify in this way for licenses without examination are required to have only a preliminary educational qualification from a secondary school and graduation from a chiropractic school of a course of study of eighteen months. This would permit a large number of chiropractors who are unqualified educationally to be licensed to engage in the practice of healing.

*By Mr Nicoll, Assembly Int No 185*—This

bill provides for adding to the present medical examining board chiropractors whose qualifications are not the subject of any test by the regents whatever. It contains the same vice as the other chiropractic bills by which the present practitioners of chiropractic are licensed without examination, irrespective of the standards of such school or how the chiropractor got his diploma. It is well known that many of them got their diplomas with practically no educational qualifications. The effect of this bill is likewise to grant licenses to diploma mill graduates. Chiropractors are given the right to use the title of "Doctor," which is a title they have never earned under any standard that has been set in this state—a title conferred by legislative act, rather than by educational qualifications. Chiropractors licensed in other states will be permitted to be licensed in this state, so that those so licensed under similar waiver clauses could come into this state and practice.

This act confers upon licensees all rights of professional persons under the Civil Practice Act and Judiciary Law and establishes them as physicians and confers the title of "Doctor" upon such licensees granting them the right to be appointed as alienists upon commissions to inquire into the sanity of persons accused of crime.

Each of these bills seeks to divest the constituted state authorities of discretion and power to determine the qualification of applicants under the waiver clause. If a man had spent the time specified in the kind of school specified and had practiced for the time specified, whether his time was well spent, the school good or bad, the practice criminal or otherwise, would be entitled to receive a license. These waiver clauses that seek to make the state accept the results of these privately-owned schools, operated for profit, without power to rate the schools or pass upon their standards and, furthermore, that make licensure utterly lacking in any real test of fitness, are wholly arbitrary, and as measures for the regulating of the practice of a branch of healing, are not in anywise adapted to the end intended, and are mere cloaks for conferring a special privilege and are in contravention of the Constitution.

These bills permit chiropractors legally to masquerade before the public by virtue of a legislative decree, as educated and trained and to pretend that they are doctors for their own pecuniary advantage.

These bills propose to grant as a special privilege to a favored class under their waiver clauses, without reference to the qualifications of such class, practically all the honor, title, privileges and rewards that physicians enjoy only after meeting the highest mental, moral and scientific tests.

The privately-owned and operated-for-profit chiropractic schools whose standards are not tested by the regents of this state, are made the

**MEMORANDUM SUBMITTED IN BEHALF OF THE MEDICAL SOCIETY OF THE  
STATE OF NEW YORK TO THE JOINT COMMITTEE ON PUBLIC HEALTH  
OF THE SENATE AND ASSEMBLY ON BILLS RELATING  
TO CHIROPRACTIC**

By **GEORGE W. WHITESIDE**, Counsel, Medical Society of the State of New York

By Mr Bouton, Senate Int No 789, entitled "An Act to Define and Regulate the Practice of Chiropactic" This bill creates a separate board of examiners for the purpose of licensing chiropactors only and establishes lower standards than those applying to other methods of healing. The adopting of a lower measure of educational qualification based upon the use of a particular method of treatment is wrong in principle, as it omits consideration of the necessity of proper educational and scientific qualifications for the purpose of making diagnosis. Fundamental educational qualifications requisite for the making of proper diagnoses cannot be omitted as a requirement for license in order to favor those engaging in a particular form of treatment.

The bill establishes a machinery for licensing chiropactors which is controlled and operated by the New York Chiropactic Society, which is composed of members whose educational qualifications have never been the subject of any tests by the regents of this state and whose fitness to perform the function of examiners is not subject to control or regulation by the regents. The board of chiropactic examiners so controlled by this society have entire charge of preparation and grading of examination papers and, therefore, of the licensing of chiropactors. Under this bill, hundreds, possibly upwards of a thousand chiropactors now practicing whose educational qualifications are unknown, many of whom are without educational standards or qualifications, would be licensed without test of their fitness. Accepting as a standard for licensure without examination, the diploma of chiropactic schools, over which the regents have no control and whose standards are unknown to the regents, is equivalent to license without standard. Any person who has received a diploma from any school teaching chiropactic, irrespective of the time spent in such school, or the standard of such school, or the previous educational qualification of the person receiving such diploma, would be entitled to be licensed without examination.

This bill practically licenses diploma mill graduates and turns them loose upon the public with a stamp of the state's approval, with a certification of their fitness, despite the fact that the state has made no test to justify the giving of such certificate. The provisions by which educational standards are set for future applicants for license has merely the effect of giving those who receive license without examination a special privilege in a non-competitive field of operation by causing a virtual exclusion of those who are not so favored.

The regents are practically made the rubber stamp of the New York Chiropactic Society and the board of chiropactic examiners in the conduct of any examinations under this act and the regents are required to select the questions to be submitted to candidates from a list of questions submitted by such examiners. So, in effect, the chiropactic society is made the licensing power. Chiropactors from other states may be licensed here without examination. This would admit large numbers who have been licensed in other states without examination.

By Mr Gibbs, Senate Int No 473 This is known as the "Drugless Practice Act." A separate board to license drugless practitioners is created. The choice of membership in this board is made from irresponsible societies, whose members have no legal right of practice or status, whose educational qualifications are unknown and untested. It has the same defects as the Bouton bill, only worse, in that it again makes licensure dependent upon the method of treatment alone. All methods of treatment, by hand or mechanically, without the use of drugs, osteopathy, surgery or Christian Science, come under this bill. Thus, the treatment of fractures, other than by open operation, would come under this bill. The use of the laryngoscope, cystoscope and oesophagoscope, which is operated by hand, would come under this bill. The passage of such a measure multiplies the number of licensing agencies in the state based upon the false assumption that the method of treatment shall be the basis of license.

Any one holding a diploma from an incorporated school or college of drugless methods, no matter how the diploma was obtained, what his educational qualifications are, how much or how little he had studied, is eligible to become an examiner, irrespective of any test by the regents. Examination papers would be made up by such an unqualified board. From the list of questions submitted, the regents would be compelled to accept therefrom the questions to be submitted to the candidate. This deprives the regents of power and places the power of examination in the hands of unqualified persons. The same unqualified persons pass upon the answers to the questions. This bill, as practically all other bills of this character, contains the usual provisions of licensing practitioners without examination. Under this bill, any person 21 years of age, who is vouched for by four citizens and who for two years has practiced drugless methods and who has a diploma from a drugless school or college, no matter how obtained or how little study was done to earn it and who pays \$25 to the board,

## 119TH ANNUAL MEETING

The regular annual meeting of the Medical Society of the State of New York will be held in Syracuse, May 12 to 14, 1925.

OWEN E. JONES, M.D., *President*

EDWARD LIVINGSTON HUNT, M.D., *Secretary*

## SUMMARY OF SCHEDULE

*House of Delegates, Monday afternoon and evening, and Tuesday morning. Section meetings, Tuesday afternoon and Wednesday morning and afternoon. Tuberculosis demonstration all day Thursday.*

## SECTION PROGRAMS

### SECTION ON MEDICINE

Chairman—ROBERT L. LEVY, M.D., New York City  
Secretary—L. WHITTINGTON GORHAM, M.D., Albany  
Place of Meeting—Hotel Syracuse.

#### Tuesday, May 12th, 2 30 P.M.

"Some Observations on Constitutional Factors in Disease," George Draper, M.D., New York City

"The Present Status of Insulin Therapy," Elliott P. Joslin, M.D., Boston, Mass. (by invitation)

Discussion opened by H. Rawle Geyelin, M.D., New York City

"The Specific Serum Treatment of Scarlet Fever," Francis G. Blake, M.D., New Haven, Conn. (by invitation)

Discussion opened by Augustus B. Wadsworth, M.D., Albany

"The Therapeutic Value of Oxygen in Pneumonia," Carl A. L. Binger, M.D., New York City (by invitation)

Discussion opened by Nelson G. Russell, M.D., Buffalo

#### Wednesday, May 13, 9 30 A.M.

Joint Session with Section on Neurology and Psychiatry

#### Symposium on "Mind and Medicine."

"Psychological Aspects of Medical Research," Thomas W. Salmon, M.D., New York City

"Mental Hygiene and Its Relation to General Medicine," Charles MacFie Campbell, M.D., Boston, Mass. (by invitation)

"Mental Factors in General Medical Diagnosis," Le-wellys F. Barker, M.D., Baltimore, Md. (by invitation)

"Uses of Psychotherapy in General Medical Treatment," Austen Fox Riggs, M.D., Stockbridge, Mass. (by invitation)

Discussion opened by George Draper, M.D., New York City

#### Wednesday, May 13, 2 30 P.M.

Joint Session with Sections on Pediatrics and Public Health, Hygiene and Sanitation

#### Symposium on "The Problem of the Chronic Cardiac Cripple."

"General Survey of the Problem," James B. Herrick, M.D., Chicago, Ill. (by invitation)

"Statistical Aspects of the Problem," Louis I. Dublin, Ph.D., New York City (by invitation)

"A Program of Procedure," Homer T. Swift, M.D., New York City

"The Organization of a Cardiac Clinic," John Wyck-off M.D., New York City

Discussion opened by Haven Emerson, M.D., New York City

#### Thursday, May 14th

Tuberculosis demonstration

### SECTION ON SURGERY

Chairman—MARSHALL CLINTON, M.D., Buffalo  
Secretary—EDWARD S. VAN DYKE, M.D., Syracuse  
Place of Meeting—Hotel Syracuse.

#### Tuesday, May 12th, 2 30 P.M.

"Etiology of Cancer," Isaac Levin, M.D., New York City

"Surgical Treatment of Malignancy," George W. Crile, M.D., Cleveland, Ohio (by invitation)

"Present Status of Radium Radiation," Burton J. Lee, M.D., New York City

"Present Status of X-Ray Therapy," Bernard F. Schreiner, M.D., Buffalo

"Present Status of Treatment of Cancer," Burton T. Simpson, M.D., Buffalo (by invitation)

#### Wednesday, May 13th, 9 30 A.M.

"Syphilis," Ralph Mellon, M.D., Rochester (by invitation)

"Diagnosis of Tertiary Lesions," Grover Wende, M.D., Buffalo

judges of fitness for license, rather than the officials of the State of New York. These institutions are not essentially educational institutions, but business enterprises. The requirement that such chiropractor shall have practiced for a given time in this state as a prerequisite to license without examination constitutes a reward for violating the present Medical Practice Act, as such practice of chiropractic is a violation of that act. In this way, these acts make a virtue of such offenses against the law and reward continuous practice in violation of the law by granting to the wrongdoer a license without examination. The diploma-mill graduate must be exempted from examination, if he can prove attendance upon a chiropractic school for the required time. The exemption clauses of these bills are not part of any

plan for the regulation of the practice of chiropractic, but constitute a grant of special privilege to certain individuals now defying the laws of this state, to whom the bills are to be a reward for their transgression, rather than a test of their fitness.

These chiropractic licensing bills are similar to all the bills that have been submitted from the same source in the last ten years and are typical of the kind of medical legislation that is made possible by popularizing, through clever publicity, scientifically false claims. The legislature should not mistake the noise and agitation of a small majority of selfish men, through systematic and well-recognized effort, in the spreading of false propaganda for expressions of popular opinion.

Wherefore, it is asked that these bills be not approved.

## HEARINGS

Wednesday, March 11—Joint Hearing before Senate and Assembly Labor and Industry Committees

Senate Int No 380 (conc Assembly Int 570) (Dunn-Farrell)—Workmen's Compensation Law, medical attendance

Senate Int No 594 (conc Assembly Int 622) (Love-Lattin)—Workmen's Compensation Law, medical attendance

Senate Int No 647 (conc Assembly Int 184) (Johnson-F A Miller)—Workmen's Compensation Law, physical examinations

Senate Int No 1078 (Reiburn)—Workmen's Compensation Law, disability

Senate Int 1103 (Reiburn)—Workmen's Compensation Law, occupational disease

Senate Int. No 1104 (Reiburn)—Workmen's Compensation Law, claims

Senate Int No 1105 (Reiburn)—Workmen's Compensation Law, presumptions

Senate Int No 1106 (Reiburn)—Workmen's Compensation Law, earnings

Senate Int No 1113 (Whitley)—Workmen's Compensation Law, subrogation

Senate Int No 1114 (Whitley)—Workmen's Compensation Law, interest

Senate Int No 1115 (Whitley)—Workmen's Compensation Law, when due

Senate Int No 1117 (Whitley)—Workmen's Compensation Law, appeals

Assembly Int No 152 (Weinfeld)—Workmen's Compensation Law, medical service

Assembly Int No 1335 (Galgano)—Workmen's Compensation Law, aliens

Assembly Int No 1350 (C P Miller)—Workmen's Compensation Law, appeals

Assembly Int No 1351 (C P Miller)—Workmen's Compensation Law, medical practice.

Assembly Int No 1354 (Phelps)—Workmen's Compensation Law, occupational disease

Assembly Int No 1407 (C P Miller)—Workmen's Compensation Law, interests

Assembly Int No 1452 (C P Miller)—Workmen's Compensation Law, define board

### Public Health Committee

March 11

Senate Int No 115 (conc Assembly Int 215) (Kennedy-Weinfeld)—Drugs, habit forming

Senate Int No 632 (J F Williams)—Health Law, Pharmacies

Senate Int No 851 (conc Assembly Int 1027) (Karle-Lattin)—Health Law, cadavers

Assembly Int No 802 (Donohue)—Pharmacies, drug stores

Assembly Int No 678 (Samberg)—Food, persons handling

9 30 A M

Assembly Int No 925 (Coughlin)—Health Law, practice medicine

Assembly Int No 1348 (Lattin)—State Medical Society, censors

Assembly Int No 1450 (Lambert)—Dental hygienist, women

Assembly Int No 1539 (Lattin)—Pharmacy, practice of

### Codes Committee

March 17

Assembly Int No 987 (Boyle)—Penal Law, Contraceptive treatment

"Mental Factors in General Medical Diagnosis,"  
Lewellys F Barker, M D, Baltimore, Md (by invitation)

"Uses of Psychotherapy in General Medical Treatment," Austen Fox Riggs, M D, Stockbridge Mass (by invitation)

Discussion opened by George Draper, M D, New York City

**Wednesday, May 13th, 2 30 P M**

"Epidemic Encephalitis and the Vegetative Nervous System," Foster Kennedy, M D, New York City

"Chronic Symptoms Following Acute Epidemic Encephalitis," illustrated by Moving Pictures, S Philip Goodhart, M D, New York City

"The Effect of Producing Aseptic Meningitis upon Dementia Praecox," Everett Sperry Barr, M D, Philadelphia, Pa. (by invitation)

"Treatment of Paresis by Malaria," Henry A. Bunker, M D, New York City (by invitation)

"New Observations upon Drug Therapy in the Psychoses," William W Wright, M D, Utica

"Mental Mechanism in Mental Disease," William C Garvin, M D, Binghamton (read by title)

"Physiological Action of Luminal, Preliminary Report on Animal Experimentation," Professor M S Dooley, M D, Eugene N Boudreau, M D, Syracuse (read by title)

**Thursday, May 14th**

Tuberculosis demonstration

**SECTION ON PEDIATRICS**

Chairman—JOSEPH C PALMER, M D, Syracuse.

Secretary—ARTHUR W BENSON, M D, Troy

Place of Meeting—Hotel Syracuse.

**Tuesday, May 12th, 2 30 P M**

Joint Session with Sections on Neurology and Psychiatry and Public Health, Hygiene and Sanitation

"The Part of Prevention in Pediatric Practice," J H Mason Knox, M D, Chief Bureau of Child Hygiene, Baltimore, Md (by invitation)

"Mental Hygiene of the Child and Its Relation to Mental Stability in Adult Life," Douglas A. Thom, M D Boston, Mass (by invitation)

"Mental Hygiene of the Child and Its Relation to the Development of Character," Ira S Wile, M D, New York City

"The Serum Treatment of Poliomyelitis," Wardner D Ayer, M D, Syracuse

**Wednesday, May 13th, 9 30 A.M.**

"Growth and Development, Their Influence Upon Normal Progress and the Expression of Disease in Childhood," Herbert B Wilcox, M D, New York City

"Pediatric Viewpoint in Treatment of Diabetes Mellitus," Roger H Dennett, M D, New York City

"Chronic Ulcerative Colitis in Childhood," Henry F Helmholtz, M D, Rochester, Minn (by invitation)

Discussion opened by Henry L K Shaw, M D, Albany

"Trichinosis in Children A Report of Cases" John Ackman, M D, Rochester

Discussion opened by W Parker Stowe, M D Rochester

**Wednesday, May 13th, 2 30 P M**

Joint Session with Sections on Medicine and Public Health, Hygiene and Sanitation

Symposium on "The Problem of the Chronic Cardiac Cripple"

"General Survey of the Problem," James B Herrick, M D, Chicago Ill (by invitation)

"Statistical Aspects of the Problem," Louis I Dublin, Ph D, New York City (by invitation)

"A Program of Procedure," Homer F Swift, M D, New York City

"The Organization of a Cardiac Clinic," John Wyckoff, M D, New York City

Discussion opened by Haven Emerson, M D, New York City

**Thursday, May 14th**

Tuberculosis demonstration

**SECTION ON PUBLIC HEALTH, HYGIENE AND SANITATION**

Chairman—PAUL B BROOKS, M D, Albany

Secretary—ARTHUR D JAKES, M D, Lynbrook.

Place of Meeting—Hotel Syracuse.

**Tuesday, May 12th, 2 30 P M**

Joint Session with Sections on Pediatrics and Neurology and Psychiatry

"The Part of Prevention in Pediatric Practice," J H. Mason Knox, M D, Chief Bureau of Child Hygiene, Baltimore, Md. (by invitation)

"Mental Hygiene of the Child and Its Relation to Mental Stability in Adult Life," Douglas A. Thom, M D, Boston, Mass. (by invitation)

"Mental Hygiene of the Child in Its Relation to the Development of Character," Ira S Wile, M D, New York City

"The Serum Treatment of Poliomyelitis," Wardner D Ayer, M D, Syracuse.

**Wednesday, May 13th, 9 30 P M.**

Session for health officers, school medical inspectors and other public health workers

Principal Discussion Limited to 5 Minutes

"How can the County Laboratory Best Serve the Interests of Physicians and of the Public," Morris Mason M D Glens Falls

"Organization of the Hornell Breast Feeding Demonstration" Bertis R Wakeman, M D, Hornell.

"Morbidity and Mortality Among Breast Fed and Artificially Fed Babies," Elizabeth M Gardner, M D, Albany (by invitation)

"The Washington County Public Health Clinic," Miss Virginia A. Kilrain, Hudson Falls (by invitation)

"The Pre-tubercular Child as a Factor in the Control of Tuberculosis," Jonathan Pearson, M D Schenectady

"The Newspaper as an Aid in Local Public Health Work," Leo F Schiff, M D, Plattsburg

**Wednesday, May 13th, 2 30 P M**

Joint Session with Sections on Medicine and Pediatrics

Symposium on "The Problem of the Chronic Cardiac Cripple"

"General Survey of the Problem," James B Herrick, M D, Chicago Ill (by invitation)

"Statistical Aspects of the Problem," Louis I Dublin, Ph D, New York City (by invitation)

"A Program of Procedure," Homer F Swift, M D, New York City

"The Organization of a Cardiac Clinic," John Wyckoff, M D, New York City

Discussion opened by Haven Emerson, M D, New York City

**Thursday, May 14th**

Tuberculosis demonstration

"Spinal Cord Tumors," Arthur H. Stein, M.D., Albany

"Regional vs. Inhalation Anesthesia in Prostatectomy," Oswald S. Lowsley, M.D., and H. Earl Rogers, M.D., New York City (by invitation)

"Resume of Prostatectomy," Parker Syms, M.D., New York City

### Wednesday, May 13th, 2 30 P.M.

"Uses of Enterostomy in Cases of Acute Ileus," Frederick van Beuren, Jr., M.D., New York City

"Pyloric Obstruction in Infancy," Thew Wright, M.D., Buffalo

"Present Status of Surgery for Ulcer," Charles H. Peck, M.D., New York City

"Study of Gastric and Duodenal Ulcers with Especial Reference to Hemorrhage," Fordyce B. St. John, M.D., New York City

### Thursday, May 14th

Tuberculosis demonstration

## SECTION ON OBSTETRICS AND GYNECOLOGY.

Chairman—HAROLD C. BAILEY, M.D., New York City

Secretary—NATHAN P. SEARS, M.D., Syracuse, N. Y.

Place of Meeting—Hotel Syracuse

### Tuesday, May 12th, 2 30 P.M.

"Idiopathic Uterine Bleeding from the Pathological Standpoint," Emil Novak, M.D., Baltimore, Md. (by invitation)

"Idiopathic Uterine Bleeding from the Clinical Standpoint," William P. Healy, M.D., New York City

"Fertility and Health," Donald Macomber, M.D., Boston, Mass. (by invitation)

"Pregnancy Following Transuterine Insufflation," Isidor C. Rubin, M.D., New York City

"Endocrine Treatment of Sterility in Women," Timothy F. Donovan, M.D., Buffalo

### Wednesday, May 13th, 9 30 A.M.

"The End Results following the Sturmdorff Operation," Harvey B. Matthews, M.D., Brooklyn

"Preliminary Report of the Radium Work at the Woman's Hospital," Lillian K. P. Farrar, M.D., New York City

"Protein Injections in Gynecological Infections," Reginald M. Rawls, M.D., New York City

"Teratomata—Ovarian and Retroperitoneal," Onslow A. Gordon, Jr., M.D., Brooklyn

"Onset of Labor," Isidor Kross, M.D., New York City

### Wednesday, May 13th, 2.30 P.M.

"Use of Paralehyd in Obstetrics," William Edgar Caldwell, M.D., New York City

"Morphine in Eclampsia," Hervey C. Williamson, M.D., New York City

"Syphilis in Pregnancy," Alfred C. Beck, M.D., Brooklyn

"Use of the Kiehland Forceps," James Knight Quigley, M.D., Rochester

"The Version and Spinal Cord and Cerebral Injuries," William E. Caldwell, M.D., and Richard N. Pierson, M.D., New York City

"Elective Version and Extraction," Paul T. Harper, M.D., Albany

### Thursday, May 14th

Tuberculosis demonstration

## SECTION ON EYE, EAR, NOSE AND THROAT

Chairman—ARTHUR G. BENNETT, M.D., Buffalo

Secretary—EUGENE E. HINMAN, M.D., Albany

Place of Meeting—Hotel Syracuse

### Tuesday, May 12th, 2 30 P.M.

"Thyroid Feeding in Pituitary Disease," Frank W. Marlow, M.D., Syracuse

"Relation of Diet to the Eye," Arthur M. Yudkin, M.D., New Haven, Conn. (by invitation)

"The Efficiency Values of Visual Acuity as Determined by the Snellen Text," Albert C. Snell, M.D., Rochester

"Rapid Muscle Testing without Apparatus," James W. White, M.D., New York

### Wednesday, May 13th, 9 30 A.M.

"Correction of Nasal Deformities," William Wesley Carter, M.D., New York City

"Bronchoscopic Treatment of Bronchial Asthma," William Moore, M.D., Philadelphia, Pa. (by invitation)

"Value of Blood Transfusion in Sinus Thrombosis," Harold Hays, M.D., New York City

"Some Nasal Problems," Roy S. Moore, M.D., Syracuse

### Wednesday, May 13th, 2 30 P.M.

"Local Anesthesia of the Eye," Edmund Blaauw, M.D., Buffalo

"Local Anesthesia of the Nose and Throat," Clayton M. Brown, M.D., Buffalo

"Local Anesthesia of the Nose and Throat by Cocainization of the Naso-Palatine Ganglion," Simon L. Ruskin, M.D., New York City

"The Clinical Significance of Orbital and Intraocular Tumors," Conrad Berens, M.D., New York City

### Thursday, May 14th

Tuberculosis demonstration

## SECTION ON NEUROLOGY AND PSYCHIATRY

Chairman—EUGENE N. BOUDREAU, M.D., Syracuse

Secretary—CLARENCE O. CHENEY, M.D., Utica

Place of Meeting—Hotel Syracuse

### Tuesday, May 12th, 2.30 P.M.

Joint Session with Sections on Pediatrics, Public Health, Hygiene and Sanitation

"The Part of Prevention in Pediatric Practice," J. H. Mason Knox, M.D., Chief Bureau of Child Hygiene, Baltimore, Md. (by invitation)

"Mental Hygiene of the Child and Its Relation to Mental Stability in Adult Life," Douglas A. Thom, M.D., Boston, Mass. (by invitation)

"Mental Hygiene of the Child in Its Relation to the Development of Character," Ira S. Wile, M.D., New York City

"The Serum Treatment of Poliomyelitis," Wardner D. Ayer, M.D., Syracuse

### Wednesday, May 13th, 9 30 A.M.

Joint Session with Section on Medicine

## Symposium on "Mind and Medicine"

"Psychological Aspects of Medical Research," Thomas W. Salmon, M.D., New York City

"Mental Hygiene and Its Relation to General Medicine," Charles MacFie Campbell, M.D., Boston, Mass. (by invitation)

before the first of January of each year may have his license revoked or suspended by the State Board of Regents."

While the Karle-Dunmore Bill does not contain this provision, it could all too easily be amended after registration was once a law—as has occurred in the case of the nurses and podiatrists

2. Section 170-d, which has to do with the use of contraceptive measures, should be restored to the bill

3 The penalties are objectionable, too severe, give arbitrary power, and in our opinion, are for contempt only

4 The bill is unnecessary, unremedial uncalled for. Our present laws are sufficient. We should go slowly about any change in the Medical Practice Act as physicians in general are not acquainted with such proposed changes

5 We should reject anything covered by existing law. We believe we would be making more laws without enforcing the present ones

6. While calling for registration of all honest physicians with payment of a fee, etc., for five years, and then registering annually for the rest of our natural lives without payment of a fee, it does not register cults

7 We believe the public health is better protected today than ever before. This bill empowers the attorney-general to deprive the district attorney of the right to prosecute—an unwarranted centralization of power

8. We have a vested interest in our state license as practitioners of medicine which should not be jeopardized by even the color of discretionary power

9 In our opinion, this bill would be an entering wedge for compulsory health insurance and other forms of State Medicine

10 The only good that might presumably be obtained now would be to prosecute cults at the cost of great personal inconvenience

About midnight your Committee cast one vote in unanimous opposition to the Karle-Dunmore Bill

(Signed) JOSEPH A. DRISCOLL, M.D.,  
*Chairman Legislative Committee*

Dr Harris Moved that the motion passed be reconsidered in order that the resolutions presented by Dr Lasher might be incorporated in the minutes and also opportunity given for discussion thereon. Seconded and Carried

Dr Harris Moved that the Council order a referendum of the House of Delegates on the Karle-Dunmore Bill Senate Int No 211, Assembly Int No 307, and that a Committee of three be appointed by the President to draw up the form to be sent to the members of the House of Delegates and canvass the vote. Seconded and carried

The President appointed the following committee: Dr Harris, Chairman, Dr Van Cott and Mr Whiteside

Dr Harris presented the following form which had been drawn up by the Committee

WHEREAS, There has been introduced in the Senate by Mr Karle a bill, introductory number 211 (see Journal, January 30th, 1925, page 123), entitled "An Act to Amend the Public Health Law in relation to the practice of medicine" and a similar Act by Mr Dunmore in the Assembly known as introductory number 307, and a hearing on these bills is to be held in the Assembly Chamber before a joint committee on Public Health of the Senate and the Assembly on March 4 1925 and

WHEREAS, These bills are sponsored by the Department of Education of the State of New York and provide for amendments to the Medical Practice Act, providing for an accurate official list of licensed physicians by means of annual registration, the clarifying of the exemptions of different classes of persons under the Act so as to limit such exemptions and make the Act more effective, providing for adequate, civil and criminal penalties for the practice of medicine by the unlicensed practitioners, prohibiting the use of the title "Doctor" by those not legally entitled to the same, curtailing improper medical advertisements, providing for recovery of damages against unlicensed practitioners for injury to those treated by them, simplifying the procedure for revocation and annulment of registration of physicians, and providing for state wide inspection and prosecution of illegal practitioners, and

WHEREAS, That at the hearing on March 4, 1925 by the Joint Committee, it is desirable that the Medical Society of the State of New York should officially record its position on said measures.

Therefore, Be It Resolved, That the Council hereby approves said measures and recommends the passage of the same subject to a favorable referendum vote of the House of Delegates of the Medical Society of the State of New York confirming said action

Further Resolved, That pursuant to Section 24 of the By-Laws of the Medical Society of the State of New York, a referendum vote of the said House of Delegates be, and is hereby ordered, and said vote shall be completed by mail on or before the 5th day of March 1925, and that the question submitted for such vote shall be as follows

The Medical Society of the State of New York hereby endorses the said Karle and Dunmore bills and urges their passage by the Legislature.

Vote by marking X in blank space

Yes [☐  
No [☐

Officer or Chairman, Standing Committee.

Delegate from  
County of the Medical Society of the  
State of New York

Note A majority vote before March 4th is necessary to be of any value. Vote and return at once to the Secretary

New York City, February 18, 1925

By order of the Council,

EDWARD LIVINGSTON HUNT,  
*Secretary*

Moved, seconded and carried that it be approved

Dr Vander Veer presented a bill which had been drawn up by the Counsel in accordance with the resolution of the House of Delegates

"That the Council, with the aid of the legal counsel, examine all the statutes, and all other acts which effect the Medical Society of the State of New York, and prepare bills to be introduced in the Legislature with the object of simplifying the operation of the law and of removing the objectionable features in the statutes and providing, if possible, a codification of the laws gov-

## MEETING OF THE COUNCIL

A meeting of the Council of the Medical Society of the State of New York was held at the State Society rooms, 17 West 43d Street, New York City, on Wednesday afternoon, February 18th, 1925. Dr Owen E Jones, President in the Chair, Dr Edward Livingston Hunt, Secretary

The meeting was called to order at 2 P M and on roll call the following answered to their names Drs Owen E Jones, E Elhot Harris, George M Fisher, Edward Livingston Hunt, Joshua M Van Cott, Frank H Lasher, Nelson O Brooks, James N Vander Veer, Orrin Sage Wightman

Mr George W Whiteside, Counsel for the State Society, and Dr Joseph S Lawrence, Executive Officer, were also present

A quorum being present, Dr Jones announced the meeting open for business

Moved and seconded that the reading of the minutes of the last meeting be dispensed with Carried

The Secretary presented letters and telegrams from Drs Arthur J Bedell, Wilham I Dean, George H Fox, Henry Lyle Winter, and Luzerne Coville regretting their inability to be present

Moved and seconded that Drs Bedell, Dean, Fox, Winter and Coville be excused Carried

The Secretary stated that Dr Williams, Director of the Academy of Medicine, had sent him the floor plan of the new building showing the space which had been assigned to the State and County and other medical societies and asking that representatives from the various societies agree upon some method of dividing the space allotted so that partitions could be arranged to suit their needs

Moved and seconded that a committee of three be appointed by the President, including the Secretary, to confer with the Academy authorities and to report at the next meeting of the Executive Committee Carried

Dr Vander Veer presented a communication from Dr Woodward, Secretary of the Bureau of Legal Medicine and Legislation of the American Medical Association in regard to the Reorganization Bill pending in the U S Senate and asking that action be taken in opposition to this bill by the State Society

Moved and seconded that it be referred to the Executive Committee Carried

Dr Vander Veer presented the program of the Annual Congress on Medical Education, Medical Licensure, Public Health and Hospitals, to be held in Chicago, March 9th to 12th, 1925, and asked if the Council thought it desirable to send a representative to this meeting

Moved and seconded that it be placed on file Carried

Dr Harris stated that the Council has been called together to take action on the bill to amend the medical practice act which has been formulated and introduced into the Legislature by the State Department of Education and refer said action to referendum vote of the House of Delegates

Dr Vander Veer moved that the Council go on record as approving the bill drawn up by the Education Department known as the Karle-Dunmore Bill

Dr Harris moved that the Council order a referendum of the House of Delegates in accordance with section 24 of the by-laws on the Medical Practice Act, and that the form of referendum be determined by a sub-committee of three appointed by the President Seconded and carried

Dr Lasher stated that he would like to present a report containing resolutions showing why the bill should not be approved

### Medical Society of the County of Kings

The following report of the Legislative Committee of the Medical Society of the County of Kings was unanimously accepted at the Stated Meeting of the Society held on February 17, 1925. It was moved, seconded and carried that a copy of the report be transmitted to all the County Societies in the State of New York, and also that a copy of the report be sent to the NEW YORK STATE JOURNAL OF MEDICINE for publication.

Ten days after the January meeting of the Medical Society of the County of Kings your Legislative Committee held a meeting to consider the 1925 Medical Practice Act, sponsored by the State Department of Education, and known as the Karle-Dunmore Bill, Senate Introductory 211, Assembly Introductory 307

Pursuant to the request of the Society, the Committee was advised by counsel for the Society, Judge John G Dyer

Judge Dyer took up with the Committee a calm, cold analysis of the new matter in the bill line by line. After the Judge had finished his analysis a lengthy discussion was entered into by the Committee. The good points in the bill were brought out. The reasons why we might support the bill are as follows

- 1 In union (with the State Society) there is strength
- 2 The penalties imposed would have a healthful effect on illegal practitioners

- 3 Under existing law the work of the Committee on Illegal Practice of the Medical Society of the County of Kings is voluntary and might not always function. Also, the activity of the District Attorney of Kings County is exceptional

- 4 The added protection to the title of "Doctor" is good

- 5 The State Department of Education would have what it wants, viz, a check-up on all doctors practising today

The objections to the bill are as follows

- 1 We are opposed to registration in principle. The principle of law applying in dentistry and podiatry is as follows

'Any dentist (nurse, optometrist, or podiatrist—Pars 199 and 201, 251-a, 278-a, 304, of the Public Health Law) whose name does not appear in the registry on or

# State Department of Health

## SUSPECTED "POLIO" PROVES TO BE BROKEN ARM

On February 13, a local health officer telephoned to the district state health officer that he had a case of suspected poliomyelitis in a child living on a dairy farm. The health officer stated that the child had lost the use of the right arm and had had a fever for about ten days.

The district state health officer replied that he would hesitate to consider a diagnosis of poliomyelitis if the case had had such a long period of fever, although he had seen relapsing cases which had lasted about the same length of time. In

view, however, of the fact that the child lived on a dairy farm, it was requested that great care should be exercised until the diagnosis was determined.

Later the health officer stated that he had discovered the patient had suffered an injury, and that the case of suspected "polio" was one of greenstick fracture of the humerus. He explained the history of fever by saying that it was probably due to "grippe," as other members of the family had suffered from this disease.

## INCREASE IN CONGENITAL SYPHILITIC CASES TREATED AT CLINICS

There is no part of the venereal disease program which makes a stronger appeal to the public than the treatment of infants and little children who have come into the world infected with syphilis. That these cases are quite prevalent and distributed in every part of the State is shown by the fact that there was not a clinic in the State last year which did not treat some cases of congenital syphilis while a number of clinics

found it advisable to arrange separate hours for the children. In addition to the clinic cases various health officers and physicians in rural districts have treated congenital cases with arsenic and mercury preparations supplied by the Division of Venereal Diseases of the State Department of Health. During 1924 an average of 251 cases of congenital syphilis was treated monthly at the state clinics as compared with 240 in 1923.

## QUARANTINE BROKEN HEALTH OFFICER HAS PARENT ARRESTED

In a small town in Oneida County, the health officer discovered that quarantine regulations were being broken in a home where scarlet fever existed. As the violations did not cease after due warning had been given, the health officer

had the father of the family arrested and brought before a Justice of the Peace. He pleaded guilty and was given a suspended sentence of fifteen days in the county jail.

## MEDICAL SOCIETY WILL ASSIST IN DEVELOPING RURAL MATERNITY HYGIENE STANDARDS

The technique of maternity hygiene work has been highly developed in many cities, and the standards established by the Maternity Center Association of New York City, after years of study and practical experience in city work are accepted generally. The rural community, however, is a comparatively new field and practical standards suitable for general application have not yet been established. With a view to developing a practical rural program and at the

same time demonstrating the value of this line of work, the department, through the Division of Infancy, Maternity and Child Hygiene, has assigned to work in Tioga County two nurses who have had special training in the Maternity Center Association. The County medical society is interested in the undertaking and has appointed three of its members to serve as a medical advisory committee.

## NO EVIDENCE OF TULAREMIA IN RABBITS RECENTLY EXAMINED

A short time ago Mr. John T. McCormick, Deputy Chief of the Division of Fish and Game of the State Conservation Commission, discovered that a number of diseased rabbits were being found in various parts of the state and ordered some of them sent to the laboratory to be examined for evidence of tularemia. Among sev-

eral received recently, one had a broken leg which had become infected, while the others were found to have multiple abscesses from which staphylococci were isolated. The abscesses resembled those noted at times in animals that have received skin infections when fighting. No evidence of tularemia was found.

erning the Medical Society of the State of New York"

Moved and seconded that the bill as drawn up by the Counsel, be introduced into the Legislature Carried

Dr Harris presented the following

#### REPORT OF THE COMMITTEE ON PUBLICATION

A meeting of the Committee on Publication was held at the State Society rooms, 17 West 43rd Street, New York City, on Saturday, December 20, 1924

Moved and seconded that the Committee approve of the "Policy of the NEW YORK STATE JOURNAL OF MEDICINE" as published on page 999 of the December issue of the STATE JOURNAL Carried.

Moved and seconded, that the educational policy of the NEW YORK STATE JOURNAL OF MEDICINE be formulated as indicated in the proposals, the developments or the events which affect the medical profession The Editor-in-Chief shall co-operate with the Committee on Legislation and the officers of the Society before sub-

mitting the policy to the Committee on Publication. Carried

Moved and seconded, that all editorials, articles or communications for the JOURNAL must be sent to the State Society office, 17 West 43rd Street, New York City, and be approved by the Editor-in-Chief, before publication, in his discretion they may be first submitted to the Committee on Publication for action. Carried

Moved and seconded, that the Executive Editor be authorized to go to Albany, as occasion requires, to obtain information on legislation for publication in the JOURNAL. Carried

(Signed) E. ELIOT HARRIS, *Chairman*  
ORRIN S. WIGHTMAN  
EDWARD LIVINGSTON HUNT

Moved and seconded that it be approved Carried

There being no further business the meeting adjourned at 4 35 P M

### RICHMOND COUNTY MEDICAL SOCIETY

A regular meeting of the Richmond County Medical Society was held at the Staten Island Academy on Wednesday, February 11, 1925

The meeting was called to order at 9 15 with Dr Presley in the Chair

Those present were Drs Mord, Diamond, Lemuelson, Buntin, Edward Klauber, Coonley, Becker, Janeway, Kingsley, Nichols, Washington, Callahan, Smith, Cochrane, Driscoll, Randall, Rieger

The minutes of the previous meeting were accepted as read

The dinner committee reported that a dinner would be given in recognition of the fortieth year of practice of Dr Walker Washington, at the Masonic Club on March 11th

The Legislative Committee spoke on the Chiropractic and the Public Health bills now pending at Albany

A motion was made that the American Medical Association be invited to hold its 1926 meeting in New York City A motion was made to go on record as favoring the Public Health Bill, including re-registration, and against the Chiropractic Bill Motion made that Dr Smith, Chairman of the Legislative Committee, be given power to answer telegrams and decide on Legislative policies of the Society in emergency at his discretion

The scientific paper of the evening was given by Dr Allen K Krause on the "Historic Relation of Tuberculosis to General Medicine," in which he traced the history and method of treatment of tuberculosis from the Phthisis known to Hippocrates to the present day The paper was thoroughly enjoyed and a vote of thanks was given to Dr Krause

The meeting adjourned at 11.20 to the Staten Island Club

---

### MEDICAL SOCIETY OF ULSTER COUNTY

A regular meeting of the Medical Society of Ulster County was held at McCabe's Restaurant, Kingston, N Y, on February 17, 1925

Meeting called to order at 9 P M by President Dr O D B Ingalls

The minutes of last meeting were read and accepted as read

A motion was duly made, seconded and carried that the Ulster County Medical Society start proceedings against Mr X for illegal practice of medicine in Ulster County, and that the Chairman of the Comitia Minora should confer with District Attorney concerning this matter

A motion was duly made, seconded and carried that the Society contribute annually the sum of twenty dollars (\$20 00) to the Physicians' Home, Inc, at Canadea, N Y

In the scientific session, Dr H L Van Nostrand, Chairman, Dr F A Johnston of Kingston, N Y, read an interesting paper on Syphilis "as is" in Kingston The paper was well thought of by all members present. Dr Johnston was urged to send a copy of his paper to the Editor of the STATE JOURNAL for publication

After the meeting refreshments were served  
J. H. Voss, *Secretary*

# State Department of Health

## SUSPECTED "POLIO" PROVES TO BE BROKEN ARM

On February 13, a local health officer telephoned to the district state health officer that he had a case of suspected poliomyelitis in a child living on a dairy farm. The health officer stated that the child had lost the use of the right arm and had had a fever for about ten days.

The district state health officer replied that he would hesitate to consider a diagnosis of poliomyelitis if the case had had such a long period of fever, although he had seen relapsing cases which had lasted about the same length of time. In

view, however, of the fact that the child lived on a dairy farm, it was requested that great care should be exercised until the diagnosis was determined.

Later the health officer stated that he had discovered the patient had suffered an injury, and that the case of suspected "polio" was one of greenstick fracture of the humerus. He explained the history of fever by saying that it was probably due to "grippe," as other members of the family had suffered from this disease.

## INCREASE IN CONGENITAL SYPHILITIC CASES TREATED AT CLINICS

There is no part of the venereal disease program which makes a stronger appeal to the public than the treatment of infants and little children who have come into the world infected with syphilis. That these cases are quite prevalent and distributed in every part of the State is shown by the fact that there was not a clinic in the State last year which did not treat some cases of congenital syphilis while a number of clinics

found it advisable to arrange separate hours for the children. In addition to the clinic cases various health officers and physicians in rural districts have treated congenital cases with arsenic and mercury preparations supplied by the Division of Venereal Diseases of the State Department of Health. During 1924 an average of 251 cases of congenital syphilis was treated monthly at the state clinics as compared with 240 in 1923.

## QUARANTINE BROKEN HEALTH OFFICER HAS PARENT ARRESTED

In a small town in Oneida County, the health officer discovered that quarantine regulations were being broken in a home where scarlet fever existed. As the violations did not cease after due warning had been given, the health officer

had the father of the family arrested and brought before a Justice of the Peace. He pleaded guilty and was given a suspended sentence of fifteen days in the county jail.

## MEDICAL SOCIETY WILL ASSIST IN DEVELOPING RURAL MATERNITY HYGIENE STANDARDS

The technique of maternity hygiene work has been highly developed in many cities, and the standards established by the Maternity Center Association of New York City after years of study and practical experience in city work are accepted generally. The rural community, however, is a comparatively new field and practical standards suitable for general application have not yet been established. With a view to developing a practical rural program and at the

same time demonstrating the value of this line of work, the department, through the Division of Infancy, Maternity and Child Hygiene, has assigned to work in Tioga County two nurses who have had special training in the Maternity Center Association. The County medical society is interested in the undertaking and has appointed three of its members to serve as a medical advisory committee.

## NO EVIDENCE OF TULAREMIA IN RABBITS RECENTLY EXAMINED

A short time ago Mr. John T. McCormick, Deputy Chief of the Division of Fish and Game of the State Conservation Commission, discovered that a number of diseased rabbits were being found in various parts of the state and ordered some of them sent to the laboratory to be examined for evidence of tularemia. Among sev-

eral received recently, one had a broken leg which had become infected, while the others were found to have multiple abscesses from which staphylococci were isolated. The abscesses resembled those noted at times in animals that have received skin infections when fighting. No evidence of tularemia was found.

erning the Medical Society of the State of New York."

Moved and seconded that the bill as drawn up by the Counsel, be introduced into the Legislature Carried

Dr Harris presented the following

#### REPORT OF THE COMMITTEE ON PUBLICATION

A meeting of the Committee on Publication was held at the State Society rooms, 17 West 43rd Street, New York City, on Saturday, December 20, 1924

sical examination? The size of the heart is of the first importance, and in determining its size, the location of the apex beat is of the greatest importance. The apex beat is the lowermost and outermost point at which a pulsation can be determined either by sight or touch. This is usually half or three quarters of an inch outside of the point of the maximum impulse.

Percussion gives doubtful information regarding the size of the heart. Always use light percussion. The X-ray and fluoroscope are of great value for they afford the only sure determination of the size of the heart.

In auscultating the heart the first thing to think of is not murmurs, but the quality of the first sound. The normal heart sound has a definite tone, duration, intensity, and quality. An impairment of the normal nature of these qualities is of greater diagnostic value than murmurs and arrhythmias.

In determining murmurs, it is important to have the patient take exercise during the examination in order to bring out all the adventitious sounds.

The electro-cardiograph may also give valuable information, and both it and the X-ray should be employed in every uncertain case.

Arteriosclerosis and hypertension are produced by the same causes that result in heart disease. The most marked cases of arteriosclerosis—the involutionary type—are not associated with hypertension, and the presence or absence of increased blood pressure does not exclude arteriosclerosis.

The physician must determine arteriosclerosis by an examination of the accessible arteries. The

radial and the brachials are the best for examination. The retinal vessels are also to be examined, and the ophthalmoscope is a valuable instrument for the determination of arterial disease.

Little is known about the cause of hypertension except that heredity is a factor, and yet increased blood pressure is of great importance in clinical medicine.

When increased blood pressure is found, the function of the kidneys is to be determined. An excellent test is that of taking the specific gravity of specimens of urine every two hours during the day and comparing them with all of the urine passed during the night. Normally there will be a variation of ten or more points, but a variation of only five points is an indication of probable renal degeneration. With nephritis the night urine is increased in quantity (normally 400-500 c c), and the specific gravity is comparatively low.

It is important that cases of heart disease be examined frequently—once in every three or six months—and that the patient's occupation and habits of life be adjusted so as to spare the tissues from wear and tear.

It is also important that the physician should follow-up those cases, and even to send them notices of the date when the next call is due. Physicians have a false sense of modesty in following them up and getting them to come for examination. A physician does not discharge his obligations to a patient with heart disease unless he sees that they are properly guided, instructed, and treated.

---

## CONFERENCE OF CHAIRMEN OF COUNTY LEGISLATIVE COMMITTEES

A conference of the chairmen of the legislative committees of the county medical societies was held in the Ten Eyck Hotel, Albany, N. Y., on Wednesday, March 4th, 1925. The chairmen from most county societies were present. Officers of the State Society, and other members interested in medical legislation, made a total of about seventy in attendance.

The conference was opened at 9.25 A. M. by Dr. Critchlow of Albany, member of the Committee on Legislation. The first speaker was Dr. Owen E. Jones of Rochester, President of the Medical Society of the State of New York, who said that the medical profession was united and active to a greater degree than ever before. Since the referendum vote of the members of the House of Delegates stood 94 to 27 in favor of supporting the Medical Practice Act, the spokesmen of the Medical Society of the State of New York would give active support of the Act in the

hearing before the joint public health committees of the Senate and Assembly in the afternoon after the conference.

Dr. James N. Vander Veer, Chairman of the Committee on Legislation of the Medical Society of the State of New York, explained the machinery of the Society. The House of Delegates was the body which was authorized by the Constitution and By-Laws of the State Society to express the policies and standards of the Society, and when the House of Delegates was not in session, the spokesmen of the Society was either the Council, which meets three or four times a year, or the Executive Committee of the Council, which meets monthly.

The House of Delegates had delegated the action on matters of medical legislation to the Committee on Legislation, which acts in cooperation with the Legislative Committees of the county medical societies. The Committee on Legislation

# NEWS NOTES

## THE HEART AND CIRCULATION

By WALTER L. NILES, M.D.,

NEW YORK CITY

Abstract of the third lecture in the symposium on Periodic Health Examinations given in the New York Academy of Medicine on January 8, 1925, under the auspices of the Medical Society of the County of New York.

The subject of the heart and circulation is becoming increasingly important, for last year in New York City organic heart disease killed three times as many people as did tuberculosis, twice as many as cancer, and fifty per cent more than pneumonia. During the past fifty years the mortality from heart disease has increased forty-two per cent, while that from tuberculosis has decreased forty-four per cent.

Many cases of heart disease are entirely preventable, and some are curable.

Infection is the cause of heart disease in from seventy to ninety-five per cent of the cases. Of these infective cases fifty to sixty per cent are rheumatic, fifteen to twenty per cent are syphilitic, and about fifteen per cent arise from focal infections.

Old age may be accompanied by sclerotic degenerations of the circulatory system, probably the result of a very large number of infections, each of which leaves its mark and finally does so much damage that crippling or death follows.

The poisons of alcohol, tea, coffee, and tobacco are minor causes of cardio-vascular disease.

We must also mention as causes of heart disease poor habits, especially indolence, obesity, and extreme exertion without preparation for the strain.

Defects of the circulatory system are sometimes congenital, and yet the defects may be the result of infections during fetal life.

Since the rheumatic group of causes of heart disease is by far the most common, it is necessary to remember some of the closely allied rheumatic infections, particularly acute tonsillitis, chorea, torticollis, erythema nodosum, and growing pains. There is also a group of cases occurring especially in small children in which there is no conspicuous joint trouble.

Are the diseases of the rheumatic group communicable? Some studies have shown that as many as fifteen per cent of cases of acute rheumatic infections are contact cases.

A practical point to be considered is that the prevention of rheumatic conditions comes from such simple means as cleaner mouths, fewer diseased tonsils and decayed teeth, early recognition and treatment of sore throats, attention to the child with aching muscles, and repeated examina-

tions of the heart after any acute infectious disease of childhood.

It is obvious that the periodic health examinations may be of the greatest importance not only in the diagnosis of cardio-vascular-renal disease itself in its early stages, but also in the recognition of its underlying causes, especially foci of infection in the head which may be detected and eradicated. These foci are to be sought in the head (teeth, tonsils, and sinuses) and also in the lungs, gall bladder, appendix, intestine, rectum, anus, uterus, and Fallopian tubes. All of these organs should be carefully searched in any comprehensive health examination.

What are the early, or pre-clinical, signs of heart disease? In young people physical signs that are evident to the physician usually precede symptoms of which the patient complains. The usual signs are those of deformities of the valves of the heart.

In older persons the subjective symptoms felt by the patient usually precede the signs discovered by the physician. It is important for the physician to give due value to the symptoms felt by the patient. Complete history taking and an analysis of the symptoms are absolutely necessary in every examination.

The first subjective symptom of heart disease is usually dyspnoea on exertion. Choking sensations in the chest and weakness of the legs may also be present. A slight, dry cough may also be an early symptom.

An important point is that the symptoms of cardiac insufficiency may be delayed for as much as twenty-four hours after severe exertion.

Pain in the heart region—stenocardia, or angina pectoris—is a common early symptom of heart disease. The terrible so-called true angina pectoris is rarely seen but mild degrees of pain are common. A heart pain felt after exercise or after a hearty meal demands serious consideration.

The first indication of serious heart disease may be paroxysmal dyspnea, or cardiac asthma, usually coming on at night and often after exertion. Edema of the legs, palpitation, vertigo, and fainting may also be early symptoms.

What are some of the early signs of heart disease to be discovered by a physician on a phy-

medicine, and the administration of first aid by a boy scout would be breaking the law. In answer to a question, he said that the practice of drugless therapy would include chiropractic. He said that if any person could pass the drugless therapy examination, he should be given a license to practice medicine in order to see what he could do, and afterward laws could be made if damage was done.

A member of the joint committee that was holding the hearing objected to the feature of the bill in which the Attorney General could supersede the District Attorney in a prosecution of an illegal practitioner, and said that if a district attorney failed to prosecute, a complaint should be made to the Governor who would order an investigation of the conduct of the district attorney's office. The same member also objected to the provision of accumulated fines and punishments, and restriction of jail liberties of illegal practitioners, and said that there was animus behind the bill, and that the bill could not be enacted if it was to prevent murder.

Dr. Downing then introduced as speakers in favor of the Medical Practice Act, Dr. Owen E. Jones, President of the Medical Society of the State of New York, Dr. Mary Dunning Rose, President of the Women's Medical Society of the State of New York, Dr. Matthias Nicoll, Jr., State Commissioner of Health, Dr. Ralph W. Williams, representing the Osteopathic Society of the State of New York, and Mr. George W. Whiteside, Counsel for the Medical Society of the State of New York. Dr. Downing also presented arguments for the Medical Practice Act.

At this point the representative of the Drugless Therapy School presented a fifteen-year-old girl as evidence of the efficacy of drugless therapy. The girl had been taken with pain, paralysis, atrophy, and contractures of the leg, in 1922, and after a few months of treatment the girl was nearly well. The speaker said, "The point is that the drugless therapists have something worth while." Later Dr. Orrin S. Wightman, Past President of the Medical Society of the State of New York, answered a question put to him by one of the members of the joint committee, and said that the girl probably had gone through a form of meningitis in which this sequence of events was known to occur. The questioner further asked, "If there was no change before treatment, and after it a change began, would you say that treatment had something to do with it?"

The Drugless Therapy bill and the Chiropractic bills were considered together, and those in opposition to them were heard first. The speakers against the bills were Dr. Orrin S. Wightman, Dr. George R. Critchlow, and Dr. James F. Rooney. These speakers were subjected to a running fire of questions which came largely from the members of the Joint Committee. Among the questions were the following: Have the doctors ever investigated the system of chiropractic and tested its usefulness?

Will you object to a waiver exempting the present chiropractors?

If a man has practiced chiropractic or any other system of healing for eight years, would he not become experienced?

If a chiropractor passed a Regents examination in medical subjects, will you let him practice in those subjects?

Is it necessary that a chiropractor shall study obstetrics?

Is appendicitis a medical or a surgical case?

If doctors are willing to admit chiropractors who can pass a Regents examination, then is not the only question to be determined that of how present chiropractors should be recognized?

Our impressions of the hearing were somewhat confusing. While the cults tried to create a partisan atmosphere which was not conducive to the settlement of the weighty questions of medical practice, yet the hearing had the very great value of allowing everybody an opportunity for the free expression of opinion.

We sat next to a jolly chiropractor who hailed from the Bay Ridge section of Brooklyn, and swapped information with him regarding the names of the speakers, and the recognition of repartee which we could not catch owing to the exceedingly poor acoustics of the Assembly chamber. This chiropractor repudiated B. J. Palmer, and all his apparatus, including the neurocalameter. He said he was a "mixer" and would use any means to get his patients well. He took only chronic cases, and turned over his diphtherias and pneumonias to medical friends. He had been in practice five years, and would be excluded from practice by the compromise proposed by one branch of the chiropractors, but he said he would do some hard studying for a few weeks or months, and would pass the Regents' examinations.

F. O.

collects information regarding proposed legislation which affects public health, and transmits it to the physicians throughout the State, mainly through the Journal and by bulletins consisting of advance copies of the matter which will appear a few days later in the Journal

The Committee on Legislation also endeavors to inform the legislators regarding the attitude of the medical profession relative to proposed bills. The Committee had accordingly called together the chairmen of the legislative committees of the county medical societies in order that they might make available the collective opinion of the physicians throughout the State, and in cases of differences of opinion, might try to reach a common conclusion.

Dr Matthias Nicoll, Jr., State Commissioner of Health, spoke of the cordial relations between the State Department of Health and the State Medical Society, and reiterated his desire to cooperate with the physicians of the State in every way. He spoke of the aggravating effects which a division of opinion among physicians had among members of the Senate and Assembly, and pointed out the possibility that the legislators would pass a bill recognizing a limited number of chiropractors—probably those who had been in practice eight years—numbering somewhat less than two hundred. He also said that a united stand for the Medical Practice Bill and no compromise with the chiropractors would show the legislators that the physicians were actuated by unselfish, scientific motives.

Dr Augustus S. Downing, of the State Department of Education, Deputy Commissioner for Professional Education, explained the procedure

that would be followed at the legislative hearing in the afternoon, and mentioned some minor changes which would be necessary in the Medical Practice Act.

Dr William A. Howe, Director of the Medical Examination of School Children, explained the objects of the bills which related to the examinations. Most of the bills simply followed the natural evolution of the scheme of medical examinations, and most of the plans are already in operation in many places, and have been found desirable.

Dr George W. Whiteside, Counsel of the Medical Society of the State of New York, made a strong plea for a united stand for the passage of the Medical Practice Act with no exemption from its provisions to any one.

At eleven o'clock the conference went into executive session, and for an hour Dr Critchlaw and Dr Vander Veer led a discussion on forty bills which had been listed on the program. A vote was taken on the attitude of the members of the conference toward the bills in which the features of the Medical Practice Act were combined with the exemptions of present chiropractors and with added sections which would require future chiropractors to conform to the same educational standards as physicians except in surgery and obstetrics. The vote was unanimous in favor of the unamended Medical Practice Act.

The conference was marked with entire harmony and good fellowship, and was a demonstration of the unity which is being attained by physicians.

The members of the conference dined together in the Ten Eyck at noon.

F O

## THE HEARING ON THE MEDICAL BILLS

A hearing on the Medical Practice Bills before the Legislature was held by the joint Public Health Committees of the Senate and Assembly on the afternoon of Wednesday, March 4, 1925, in the Assembly Chamber. It was attended by the chairmen of the legislative committees who had been holding a conference in the morning. About one hundred representatives of the chiropractors and drugless therapy cults were also present. The chamber was well filled, and many onlookers were standing, but the room could not be considered crowded.

The hearing was begun in a dignified way by the presentation of arguments against and for the Medical Practice Act. Dr Augustus S. Downing, Assistant Commissioner and Director of Professional Education had charge of the speakers' program, and at the outset, he invited any physician who was opposed to the Bill to present his argu-

ments. The one physician who responded said his objections were along three lines: 1, Section 170-d, relating to contraceptive measures, was not in the Bill; 2, the Attorney General should not have the power to supersede the County District Attorney; and 3, the annual re-registration feature was unnecessary because there were other ways of securing lists of active physicians.

A representative of the Professional Guild presented the ten objections which were originated by the Legislative Committee of the Medical Society of the County of Kings, and which were printed on page 349 of the February 27th issue of the Journal.

A representative of a school for drugless therapy said that the Medical Practice Act defined the practice of medicine in such a way that many things now done in households, such as taking one's temperature, was the practice of

# THE DAILY PRESS

The sanitary quality of oysters continues to receive attention in the daily newspapers, although now the articles are rare. The *New York Times* of February 20th contains an account of a national conference on the subject of oyster pollution which was held in February 19th in Chicago. This conference adopted the following suggestions:

1 The beds on which shellfish are grown must be determined, inspected and controlled by some state and federal official agency

2 The plants in which shellfish are shucked or otherwise prepared or packed by the shipper must be inspected and controlled by some state and federal official agency

3 The freedom from typhoid bacilli of the workers who handle shellfish must be determined by some official governmental agency

4 Failing to secure sufficiently high standards to protect the people as regards beds, floating and plumping practices and methods of shucking or other methods of preparation, a satisfactory practical method of pasteurization or other heat treatment, or chemical, or biological method which produces satisfactory results, must be installed and operated under proper governmental supervision

5 There must be such governmental supervision and such trade organization as will make plain the source of shellfish and will prevent shellfish from one source being substituted for those from another source. This will be chiefly a problem of the individual state

6 The methods of shipping must be supervised, inspected, controlled and approved by the proper official federal and interstate agency

7 The methods of storing, displaying for sale and dispensing must be determined, inspected and controlled by the proper state or city agency

8 The product must conform to an established bacterial standard, and must meet federal, state and local laws and regulations relative to salinity, water content, food proportion and conform to the Pure Food Laws standards. There should be a revision of the existing bacteriological standards for oysters."

We have assurances from some of the large growers of oysters that they are in favor of regulations and inspections by which the quality of oysters may be "certified" by official authority in the same way that milk of the highest grade is certified. If these suggestions are carried out, buyers of oysters may be assured of the wholesomeness of oysters which they buy, and will purchase them in greater quantities than ever before.

The *Brooklyn Citizen*, February 23d, comments on the use of disease germs in war and quotes Dr. W. H. Park, chief of the Bureau of Laboratories, New York City Department of Health:

"Annihilation of millions by disease germs might sound simple to the layman, but Dr. Park thinks execution of such a plan would be very difficult. For one thing, he points out, healthy persons are continuously resisting disease attacks and many adults are immune.

"For another, there would be quite a problem to scatter them. If by explosive bombs, the heat of the explosion would make them sterile. If released from airplanes, much time would elapse before they reached the earth, and the air and sunlight very likely would make them inert.

"Then, too, an enemy would have to prepare himself against whatever bacteria he planned to use. All his forces would have to be immunized.

"It might even be that an entirely new disease would have to be discovered, such is the resistance we have built up against most of the known ills."

The *Binghamton Press*, February 19th, contains an editorial which is suggestive of ways in which medical organizations may make the influence of physicians felt in the community. The editorial criticizes the Committee on Law and Health of the Common Council for its failure to take action regarding fire risks in tenement houses, and meat inspections. The Editor says:

"The members of the committee not only have invited that attention but have fairly forced it upon themselves by their method of handling two or three important measures committed to their tender care.

"Crowded apartment buildings exist in this city without fire escapes. This is contrary to the spirit of the regulations passed by the council, and is contrary to the express letter of one of its ordinances.

"But, since there is a conflict between sections of the law, it is necessary to draft a new measure.

"Following the fatal fire at Court and Carroll Streets steps were taken to correct the faulty ordinances. A new measure was presented in the council and was referred, as a matter of form, to the committee on law and health.

"There it has remained to this day.

"We don't know whether the meat inspection measure is more important than the proposal for fire escapes. It is charged (and nobody cares to deny it) that the food inspectors of the city are powerless to enforce the law against the bringing in of impure meat for city consumption.

"They are given authority in an ordinance

## THE GORGAS MEMORIAL

The Gorgas Memorial has been endorsed by practically every outstanding scientific medical organization in the United States. At the 75th annual session of the American Medical Association, June 9-13, 1924, the following resolution was duly passed

*"Resolved, That the House of Delegates of the American Medical Association, convinced of the great promise which the Gorgas Memorial contains of benefit to humanity through improved knowledge of preventive medicine and tropical disease, and of its peculiar adequacy as a tribute to our great leader and sanitarian, recommend to the organized profession of the country, through its constituent state and county societies, the enthusiastic support of the project*

*"J A Witherspoon, Tennessee*

*"Joseph Rilus Eastman, Indiana*

*"Thomas Cullen, Maryland*

*"W H Mayer, Pennsylvania*

*"F B Lund, Massachusetts*

*"Chairman"*

Among other organizations endorsing the Gorgas Memorial are The Fifth International Conference of American States, The Society of Alumni of Bellevue Hospital, American College of Surgeons, American Dermatological Association, American Laryngological Association, American Public Health Association, American Society of Tropical Medicine, American Association of Industrial Physicians and Surgeons, Medical Women's National Association, Congress of States, American Institute of Homeopathy, Southern Medical Association, Southern Surgical Association, State Health Officers, State and County Medical Societies, Tri-State Medical Association (Wisconsin, Iowa, Illinois), Southern Commercial Congress, Daughters of the Southern Confederacy

As far afield as Seattle, Washington, comes an interesting endorsement of the work of the Gorgas Memorial. We quote from a recent issue of the bulletin of the Kings County Medical Society

*"The Work of the Gorgas Memorial Fund being based on modern business principles, should be supported by the medical profession*

*"Through the income from \$5,000,000 the Gorgas Memorial is going to make a definite organized effort to 'familiarize the public with such facts as will enable it to recognize the fallacies of the cultists*

*"A constant fund of proper health information carried to the individual through the pages of his daily newspaper, the columns of the general magazines, by means of moving pictures, lectures,*

*and the radio, will direct him to the proper source for medical advice and gradually eliminate these irregulars'*

*"Twenty-five per cent of the Gorgas Memorial work may be classed as potential and considered under the head of Pre-Clinical Medicine. The day is not far distant when the physician will keep his patients fit by means of periodic health examinations, by proper hygienic advice, and by the practical application of health and dietary knowledge. Pre-clinical medicine already forms quite a part of the work of the obstetrician and pediatrician*

*"A report of the Metropolitan Life Insurance Company demonstrated that people who have a periodic health examination and follow the advice given, have a death rate 28 per cent less than people who are not examined and advised*

The Gorgas Memorial has to date 2,500 scientific medical men on its various State Governing Committees throughout the United States. This number will be gradually increased to 5,000 as it is essential that the control of the organization be in the hands of the medical profession. Each committee is formed on a basis of 75 per cent scientific medical membership. Representative of the lay membership of the organization are Adolph Ochs, owner of The New York Times, Mr Bernard Baruch, financier, Mr Haley Fiske, President of the Metropolitan Life Insurance Company, and Mr George Gordon Battle, New York City

It is the purpose of the Gorgas Personal Health movement, controlled by the medical profession, to operate in close co-operation with influential laxity

News items of interest to New York members of the Gorgas Memorial are. First, that leading newspapers throughout the country are featuring a 'Gorgas Better Health Column,' being talks by well-known physicians and surgeons on current health problems

Dr George David Stewart is to make an address the evening of March 18th at a public forum at the Fifth Avenue Hospital, New York City, entitled, "The Gorgas Memorial Personal Health." Dr William Francis Honan will discuss Dr Stewart's paper

On March 20th, at 7 P M, Dr Stewart, who is Chairman of the Gorgas Memorial New York State Governing Committee, will launch the Gorgas radio program by a short address over WEF

Dr Edward Sherrerd Rimer is to speak before an assembly on "The Gorgas Memorial" Sunday afternoon, March 22nd, at the home of Mrs William G Willcox, Staten Island

## THE INCIDENCE OF INFECTIONS IN TONSILLECTOMIZED CHILDREN \*

By ALBERT D KAISER, M.D

ROCHESTER N Y

ONE of the common causes given for the removal of tonsils is the prevention of infections related to the tonsils. It is generally assumed that the removal of tonsils will lessen the chances for the repetition of infections or prevent certain ones where they have not occurred before. Inasmuch as tonsillectomy is performed on an increasing number of children each year, the incidence of certain infections should be lessened, provided this assumption is warranted.

There is practically no difference of opinion as to the justification for tonsillectomy where the tonsils are definitely obstructive or obviously causing repeated throat infections. However, where tonsils are removed because they appear diseased and yet are causing no particular discomfort to the child there is room for debate. But this is the type of child that is subjected to tonsillectomy in the great majority of cases. They represent the so-called average child and not the extreme case recommended for operation. Our study is based on the average operated child and not on the children who showed definite disease before operation.

The opportunity to observe a large number of operated children was given in a special clinic organized to examine and operate on about eight thousand children. At the time of operation a careful history of previous infections was taken from the parents and the child was given a complete physical examination. The children were selected from all the school children, about forty thousand being examined, either because their tonsils and adenoids appeared obstructive and diseased or because the child's history suggested tonsillar infection. Twelve hundred of this operated group were examined three years after operation and the incidence of infection ascertained during this period. At the time of the clinic a large number of children who were recom-

mended for operation for the same reason as those who were operated on failed to accept the invitation for various reasons. They have continued in school along with the operated group exposed to the same infections. From this group have been taken twelve hundred children as controls in our study. They have been examined three years after the recommendation for operation and the incidence of infection learned. A comparison of these two groups as related to infections during the last three years has been made. Consideration has been given to local infections, such as sore throat, head colds, infected ears and swollen glands, to respiratory infections, laryngitis, bronchitis and pneumonia, to general infections, measles, scarlet fever and diphtheria and to the rheumatic syndrome, rheumatism, chorea and cardiac disease.

The most common infection in the operated child elicited at the time of operation was frequent attacks of sore throat and tonsillitis. Out of the 1,200 operated children, 674, or more than half of the group, had been subject to tonsillitis previous to operation. During the last three years since the operation only 10 per cent complaining of this symptom failed to get relief from the operation.

Frequent head colds were complained of by nearly half of the children in this group previous to operation. During the last three years 146, or 27%, were still subject to frequent head colds. Obviously head colds are not eliminated when tonsils and adenoids are removed.

Enlarged or swollen cervical glands are generally looked upon as due to infections originating in the throat, ears, teeth or scalp. The presence of enlarged glands is frequently the chief indication for the removal of tonsils. It is indeed a common infection in children, for in the 1,200 operated children there was evidence of enlarged cervical glands in 81% of the children. Of this number 66% were only moderately enlarged, while 15% were consid-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester April 23, 1924

which was introduced in the council three or four months ago. But this ordinance was referred to the same committee, and the committee has made no report on it."

Law and Health matters make a curious mixture for one committee to handle. The lawyers look backward to see what some one has written about a subject in a book years ago. Physicians go to the research workers who have made investigations of the subject within the last few months.

A lawyer bases his action on *precedent*, or what has been said and done in the past. A physician creates his own precedent by up-to-date research.

Probably the physicians of Binghamton have not been consulted regarding either fire risks or meat inspections. The officials of the Medical Society of the State of New York are reiterating the suggestion that those who have charge of public health matters shall consult the physicians regarding their plans of action. They are also urging the physicians through their societies to offer their services in solving public health problems. We believe that in the face of the present criticisms of the daily press, the officials of the city of Binghamton would be willing that the organizations of physicians should assume some of the burden of responsibility for the solution of the health problems of the city, and that the physicians would be willing to advise the city fathers if their opinions were sought, or assurances were given that the advice would be welcomed.

The New York *Sun*, February 23, contains an editorial comparison of the death rates of London with those of New York City, and says

"The London County Council's report on public health is being made the basis for the assertion that the British capital is one of the healthiest of great cities. The statistics for 1923 show a death rate of only 11.4 per 1,000 of population, and an infant mortality rate of only 61 per 1,000. London and New York have been running a close race in health statistics for some time. The figures quoted above give the former city a slight advantage.

"New York expects to reduce her present death rate. Organized work for health here has been largely responsible for cutting down in twenty-five years a general death rate from 20 or more per 1,000, to less than 12. The future holds promise of reductions fully as astonishing. Meanwhile, it is rather a fine thing that the two largest cities in the world should show health statistics better by far than that of most country districts in their own nations (the death rate for the United States was 12.3 in 1923, and that of the United Kingdom (1920) 12.8), and better than the statistics for most of the civilized countries of the world. The modern city has its great

health problems, but it is making headway with them as never before."

Americans and Englishmen have a high sense of personal liberty and individual independence, and yet the greatest advances in public health are among the people of these two nations. The explanation is that both people also have a high sense of regard for the rights and opportunities of the "other fellow." The great progress in health matters in the past has been along the lines of sanitation, and the control of communicable diseases by means of governmental agencies, both by assistance and compulsion. The present methods in the United States consist largely in education of the young by public agencies, with a big compulsory factor still in use, as in the medical examination of school children.

The greater progress in store for the future will probably be along the lines of the voluntary adoption of health measures by all persons, adult as well as children. This is the aim of the campaign for periodic health examinations. An increasing proportion of governmental budgets of the future will probably be for the promotion of health.

The New York *Times*, February 22d, contains an editorial on "Where Our Taxes Go," and says that health matters account for 14 per cent of the budget of New York City. The allied activity of charity takes 7 per cent, that of education and recreation takes 31 per cent, and fire protection, 7 per cent.

The *Times* then comments on the various items of expenditure of the Federal Government, and says

"It is at Washington that we encounter an expenditure of nearly 30 per cent in interest on the public debt, nearly 20 per cent on army and navy, nearly 15 per cent on veteran rehabilitation. These are the items which account for the familiar graphs showing that perhaps 75 per cent of the taxes paid to Washington go, as the phrase has it, for past or future wars. With this expenditure are contrasted the ridiculous sums devoted by the Federal Government to education, health and other constructive services."

It is often said that three-fourths of our national expenditures go for activities based on the destruction of life. The *Times* editorial goes on to explain this condition.

"If the municipality spends 80 per cent of its taxes on constructive service and the Federal Government spends only 20 per cent, the reason is found in the division of functions as between local and Federal Government. Washington spends comparatively little on education because that has been virtually left to the municipalities and States. The cities spend little on army and navy and past wars because that has been left to the nation."

adenoids is probably the big factor in reducing the incidence of this infection

Enlarged cervical glands were found in 1,056 of the 1,200 control children. All glands have been considered enlarged that are easily palpable. This infection would be dependent upon the season, but both groups of children were examined during the same months so that the comparison is reliable. Of this large number of children with palpable glands 158 showed glands considerably enlarged. At the time of operation 179 of the operated children had large cervical glands. The operation had reduced this number to 54 as against 158 in the unoperated group. Conditions other than infected tonsils might cause swollen glands. It was found that the teeth of the unoperated group were in as good condition as the tonsillectomized children. The high incidence of swollen glands in the two groups would seem to indicate that a tonsillectomy does not prevent the swelling of the glands nor do they rapidly subside after tonsillectomy. However, there is definitely a lessened incidence in the operated group which suggests that a certain percentage of children with enlarged glands are infected through the tonsils.

Discharging ears were reported to have existed in 75 of the unoperated during the last three years while in the operated group 42 children had discharging ears. The tonsillectomized child is not immune to ear trouble although the chances for obtaining infected ears is somewhat lessened.

Recurrent attacks of laryngitis were not effected by the operation. In the unoperated group there were 112 children subject to these attacks as against 57 in the operated group. Tonsillectomy does not lessen the chances for attacks of laryngitis.

Bronchitis occurred in fewer of the unoperated than in the operated group. The same is true of pneumonia. Pulmonary infections do not appear to be influenced by tonsillectomy. It so happened that no cases of lung abscess developed in the 1,200 children studied, but this unfortunate complication does occur. The incidence is about one lung abscess in 2,000 operations in our series.

Scarlet fever had been reported in 97 of the 1,200 unoperated children and in 97 operated children. It is not likely that tonsillectomy offers any great chance to escape this infection, but the tonsillectomized child should be better prepared to withstand the throat manifestations of this disease.

Measles was found to have existed in more of the operated than unoperated children. Removal of the tonsils confers no immunity to withstand this infection.

Diphtheria was reported in 83 unoperated children and 56 operated. Only three cases

had occurred since the operation. It would seem that the tonsillectomized child is less likely to develop this disease probably because there is less opportunity for the diphtheria bacillus to grow.

Much is hoped from tonsillectomy in reducing the incidence of the so-called rheumatic syndrome. Many years must elapse before definite conclusions can be drawn as to the real value of tonsillectomy in preventing these infections. Chorea had existed in seven of the unoperated children and in eight of the operated. Six of the eight children developed it since the removal of the tonsils. A history of rheumatism, joint pains or growing pains was obtained in 128 unoperated children and in 129 operated. Of the operated group 116 developed their trouble since the removal of the tonsils. Cardiac disease was based upon the physical findings. In the control group 52 children presented evidence of cardiac disease while in the operated group there were 44 cases, of which number 13 had developed since the operation. Considering these facts no great decrease in the incidence of the rheumatic syndrome can be expected. With the marked lessening of the incidence of tonsillitis, it is hoped that cardiac disease will be less common in the operated children as the years go on.

An attempt has been made in this study to determine if tonsillectomy protects a child from the common infections. The average operated case has been compared with the same type of child who was denied operation. Based on the data collected, one must conclude that—

(1) Tonsillectomy offers great relief from attacks of sore throat and tonsillitis.

(2) It offers considerable relief to the child subject to head colds, especially where much adenoid tissue is present.

(3) It will lessen the chances for glandular infection, but is no guarantee against it nor does it assure the immediate disappearance of large glands.

(4) It lessens the chance for ear infections, but they do occur frequently in spite of it.

(5) It does not influence favorably or unfavorably infections of the larynx, bronchi and lungs, as they occur in both groups.

(6) It does not prevent scarlet fever or measles, but may influence the severity of the infection.

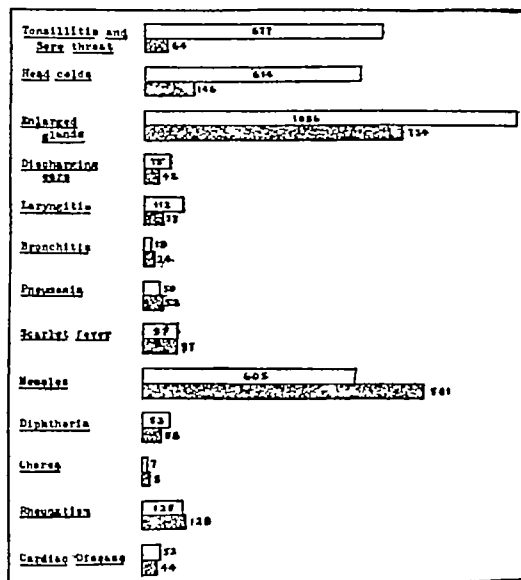

(7) It seems to lessen the incidence of diphtheria by removing fertile soil for the diphtheria bacillus.

(8) It has not influenced the incidence of chorea or rheumatism.

(9) It has shown a lessened incidence of heart disease over a period of three years.

erably enlarged. A previous re-examination of these children showed that there was no great reduction in the incidence of swollen glands one year after operation, but in the next two years there was a considerable reduction, for at the end of the third year after operation the incidence had been reduced to sixty per cent. The 15% incidence of large cervical glands has been reduced to 4.5%. Since the operation 48 children, or 4%, who had never had swollen glands before developed enlarged cervical glands.

White areas—unoperated  
Shaded areas—operated

Incidence of infection in 1,200 tonsillectomized children and the same number not operated on

Discharging ears is a common complaint in a child and frequently given as a reason for tonsillectomy. Out of the 1,200 operated children 136 had a history of either acute or chronic discharge from the ears. During the three years subsequent to the operation 42 children had a similar complaint. Of this number 26 had discharging ears for the first time after their tonsillectomy.

Chronic hoarseness or laryngitis had been complained of by 54 of the children before operation. No improvement was found in the operated children, for three years later 57 children still complained of chronic laryngitis. Only four of this number had developed it since their operation.

At the time of operation it was learned that 69 children gave a history of repeated attacks of bronchitis. The incidence of this infection during the three years following operation was 24 cases, 18 of whom had their repeated attacks since the operation and never any before.

Pneumonia had existed in 44 of the children

previous to operation and eight cases had been reported in this group since operation.

Before operation 93 children had had scarlet fever. Within the last three years since the operation four cases of scarlet fever have developed.

Measles had infected 800 children before operation, so a high incidence would not be expected since operation. Forty-eight children contracted measles since their operation.

Before the operation 53 children were reported to have had diphtheria. During the last three years since the operation three cases of diphtheria developed.

Chorea had existed in two children before operation. During the last three years six cases had developed in the operated children.

A history of joint pains, growing pains and rheumatism was obtained from 46 children previous to operation. Three years later 129 had similar complaints, and of this number 116 had their first attack of rheumatism after the operation.

Cardiac disease existed in 31 of the 1,200 operated children. This was based on physical examination and not on history. Three years later examination of the same group revealed evidence of cardiac disease in 44 children showing 13 new cases in tonsillectomized children.

It would seem from these figures that since the operation the incidence of most infections has been lessened during the three year period. However, in order to be sure that the improvement was not due to something else other than the operation an equal number of children of approximately the same ages and station in life in whom the tonsils had not been removed were studied. The control children received the same type of examination, and the history was taken in a similar way. It must be borne in mind that these controls were candidates for operation three years before, but for lack of interest on the part of the parents were never operated.

Tonsillitis and sore throat was one of the most common infections before operation. A marked decrease in the incidence was noted during the three years subsequent to operation. Of the 1,200 unoperated children 677 complained of sore throat as against 64 of the tonsillectomized children. Obviously the incidence of this common infection is favorably influenced by tonsillectomy.

Frequent head colds were reported in 614 of the unoperated children. In the same number of operated children 146 were still subject to frequent head colds. The incidence of head colds is by no means eliminated by a tonsil and adenoid removal, but about two-thirds of the children have had relief from this infection subsequent to operation. Removal of

(4) Often the pain fails to involve the whole segmental area of the skin, but finds expression in one or more points of maximal tenderness and spontaneous pain

Cope of London has attempted to establish a localizing correspondence between the part of diaphragm irritated and the part of shoulder to which pain is referred. However, in most of our cases the pain has been on the right side and usually at the outer border of clavicle

*Clinical Findings*—The medical man is well aware of the referred pain in the abdomen due to chest pathology, but few surgeons note little connection between pain in shoulder and abdominal pathology

However, phrenic nerve pain is not peculiar to free fluid in abdomen but may be due to any condition that irritates the diaphragm. The following is a list of conditions in which shoulder pain is described: pneumonia, pleurisy, pericarditis, pulmonary infarct, actinomycosis of lung, liver abscess, perforated gastric or duodenal ulcers, subphrenic abscess, cholecystitis with peritonitis, perforated gall bladder, perisplenitis, rupture of spleen, acute pancreatitis, appendicitis, ruptured intra-uterine pregnancy, pressure of drainage tube, and supra-renal tumor

In reviewing the cases I will illustrate a few which are typical for the different lesions

*Perforated Duodenal Ulcer*—T R, age 30, admitted 3/16/23

Always in good health, no indigestion, no previous stomach trouble

Suddenly seized about 3 hours after dinner with sharp pain in pit of stomach. Was taken home and put to bed. Pain in stomach became worse every minute—took some peppermint water, but no relief

Two hours later I saw him at his home—his mother was putting on hot packs to his right shoulder and he was crying out with terrific pain in stomach and a deep boring pain in right shoulder (acromio-clavicular joint). He said the pain in shoulder just started about an hour previously

On examination patient's temperature was 98°, pulse, 120, respiration, 20, it was impossible to make a physical examination because of intense pain. He dreaded to have anyone touch him, except to put on hot packs to shoulder which he said seemed to help a little

His abdomen was as rigid as a board and very little examination was allowed, a diagnosis of perforated ulcer was made. He was given morphine gr  $\frac{1}{2}$  and taken to the hospital and immediately operated by Dr McMullen, who found

a ruptured duodenal ulcer with abdomen full of peppermint water, etc

The ulcer was closed with Mattress & Lambert sutures and patient made an uneventful convalescence. He has had no further trouble

Mr J S, age 40

Had stomach trouble for years. Had two previous operations—one for appendicitis with no relief, later for a suspected ulcer. At both operations it was impossible to find an ulcer

Patient went to work in morning, two hours later suddenly had sharp pain in pit of stomach. Taken home and put to bed. Family doctor was called who prescribed some salts because bowels hadn't moved for two days. Immediately on drinking salts patient became almost maniacal with pain. The doctor gave him  $\frac{1}{4}$  gr morphine with little result, 10 minutes later gave him another  $\frac{1}{4}$  gr, 15 minutes another  $\frac{1}{4}$  gr, but pain was not relieved. Family doctor called me to see this case of supposed intestinal obstruction

On entering the bedroom I noted the patient was doubled up in bed, but would not move an inch to allow an examination. He had such pains all through his abdomen it was impossible to persuade him to turn flat on his back

I asked him about any other pain, but he wasn't inclined to talk. On further inquiry as to pain in his shoulder, he said he had such a burning pain in his shoulder he couldn't let anyone touch it (placing my hand on abdomen—it was flat and board-like)

A diagnosis of perforated duodenal ulcer was made and he was immediately taken to hospital. I found a small perforated ulcer on posterior wall of duodenum, which I closed with Mattress & Lambert sutures

He made an uneventful recovery, but has had some stomach trouble from time to time

*Case of Perforated Gall Bladder*—Mrs C R., age 50, admitted 4/9/23. Well nourished, repeated attacks of gall bladder trouble with jaundice, etc

Twenty-four hours before admission patient started to vomit, had cramps all through abdomen, fever 101, later pain localized in right lower side

Four hours before admission patient suddenly seized with sharp pain in right upper quadrant with severe pain in her right shoulder, which she said was a heavy boring feeling

On examination patient was markedly tender all over abdomen, more marked in right lower quadrant. I made a diagnosis of acute appendicitis while Dr McMullen thought she had a perforation of duodenum or gall bladder

A right rectus incision revealed no gas on opening the peritoneum, but there was a peculiar

<sup>4</sup> Cope. Clinical study of Phrenic Shoulder Pain. Brit Jour Surgery 10 1922—Oct. 1922

# IMPORTANT SYMPTOM OF PERFORATION WITH FREE FLUID IN ABDOMEN\*

F F McGAULEY, M D,

SCHENECTADY, N. Y.

**I**T is customary when called to examine a patient who has a severe intra-abdominal condition to focus all our attention on the abdomen and overlook a very important and fairly constant symptom not in the vicinity of the umbilicus. I refer to pain in the shoulder, not over the scapula, but over the acromio-clavicular joint, usually on the right but occasionally on left side and may even extend across the clavicle to the sternal border.

In reviewing the office records of Drs McMullen, Lenz and myself for past four years, which included 1,100 abdominal operations I found 28 cases of acute perforations. Analyzing these histories and studying their follow-up cards it is interesting to note that 16 or 57 per cent of the cases had pain in shoulder, especially over the outer end of the clavicle.

Practically all of the cases which we have had in the past two years have had history of shoulder pain, because we have asked direct questions at the time. Previous to that time little note was made of this condition, and on re-examination many patients do not remember much about pain in the shoulder, because the abdominal pain was so intense at the time.

Before discussing the typical case records, it might be interesting to study the reason for shoulder pain which is best brought out by a study of the embryology, anatomy and physiology of the diaphragm and phrenic nerve.

**Embryology**—In reviewing the embryology of the diaphragm Dr Mall<sup>1</sup> has stated that in its development the whole diaphragm wanders from the head to the abdomen, passing by, as well as modifying the structures and organs along the way. In the head region of the early embryo lies the anlage of the diaphragm together with those of the heart and liver. In fact the three embryonic body cavities, pericardial, pleural and peritoneal arise from the embryonic head and neck region and descend to their anatomic positions during developments.

The phrenic nerve which arises in the cervical region enters the diaphragmatic anlage and as the organ descends, lengthens to give it innervation.

Keeping this in mind, we can better understand the innervation of the diaphragm by the phrenic nerve.

**Anatomy**—The phrenic nerve has its origin from the 3rd, 4th and 5th cervical nerve roots. It is known to have both motor and sensory fibers.

It supplies sensory branches to both pleural and peritoneal surfaces of diaphragm, except at the border of diaphragm where both surfaces receive innervation from 6-12th intercostals.

**Physiology**—Capps & Coleman<sup>2</sup> have recently studied the pain produced by irritating the under surface of the diaphragm by means of a wire introduced through a cannula in patients having ascites or pneumo-peritoneum.

They conclude that pain induced by stimulation of the diaphragm is never located in the diaphragm itself, but it is referred to some distant part.

As anatomists find the phrenic nerve is chiefly made up of fibers from the fourth cervical nerve, we can understand the greater frequency of pain in the fourth cutaneous segment.

There is every reason to suppose that the different impulses from the diaphragm are carried up the phrenic nerve to the cervical cord where painful stimuli are set up in the corresponding cutaneous segment.

The neck pain from the parietal surface of the diaphragm is a typical referred pain.

The area of pain localization described both clinically and experimentally were for the most part in the distribution of the fourth cervical cutaneous segment (trapezium ridge and acromion region).

In studying the physiology of the phrenic nerve and other nerves supplying the diaphragm, the general laws of the production and distribution of visceral pain as outlined by Head<sup>3</sup> have here direct practical application. Referred pain from the viscera has been summarized in four statements.

(1) It is often remote from the site of irritation.

(2) It follows the lines on the skin of the spinal segmentation rather than the course of the peripheral nerves.

(3) It is usually associated with cutaneous hyperaesthesia and tenderness to pressure.

<sup>2</sup> J. A. Capps & G. H. Coleman—Exp. Observation on Localization of Pain Sense in the Parietal & Diaphragm Peritoneum. Arch. Int. Med. 30:778—Dec. 1922.

<sup>3</sup> Head—Disturbance of Sensation with special reference to pain of Visceral Disease. Brain 16:1—1893.

Four hours before admission patient suddenly seized with sharp pain in right upper quadrant with severe pain in her right shoulder, which she said was a heavy boring feeling

On examination patient was markedly tender all over abdomen, more marked in right lower quadrant. I made a diagnosis of acute appendicitis while Dr McMullen thought she had a perforation of duodenum or gall bladder

A right rectus incision revealed no gas on opening the peritoneum, but there was a peculiar

\*Cope. Clinical study of Phrenic Shoulder Pain. Brit Jour Surgery 10 192—Oct 1922

greenish-yellow fluid in peritoneal cavity On examining the appendix there was a large acutely inflamed appendix about three times normal size, which was removed The upper quadrant was explored and a small hole was found in the gall bladder which was full of small stones The gall bladder was also removed

The patient made an uneventful recovery

Mr J M, age 25, ex-service man Walked into the Ellis Hospital complaining of cramps on stomach

He said he had been feeling badly for two days and finally had taken a dose of salts about six hours before admission He had vomited several times

Patient had temperature of 101°, pulse 90, respiration 26 He was put to bed and about two hours later the interne "thoroughly" examined him and made a diagnosis of acute appendicitis A few minutes later the interne was called back to the room because the patient had such pains in stomach The interne ordered  $\frac{1}{4}$  gr morphine and called me to the hospital About a half hour later I saw the patient who was crying out with pain all through his stomach and had such a burning heavy pain in right shoulder just at outer edge of collar bone It was impossible to touch patient except to feel a board-like abdomen A diagnosis of acute ruptured appendix was made and patient was brought immediately to operating room

It was with difficulty the patient was anesthetized A right rectus incision was made—as soon as peritoneum was opened a gush of watery fecal matter came out Several large sponges were used to clean out some of the fluid and the appendix was exposed as quickly as possible At the base of the appendix was a large hole out of which the fecal material was pouring I immediately put a clamp on the base of the appendix and most of the fecal matter was sponged out of the peritoneal cavity The appendix was then removed and several drains inserted The next day patient felt relieved—he had no pain either in abdomen or right shoulder However, he developed pneumonia, probably embolic and expired the following morning

*Ruptured Ectopic*—Mrs J T, age 33, admitted to Ellis Hospital 12/23/23, married 12 years, one child 10 years old, no miscarriages Periods always regular up to last two months Has had slight show for past month

Twenty-four hours before admission, awoke in morning with sudden pain in her left shoulder

—did not vomit but felt nauseated Got up that morning, but did not feel good Said she felt a little weak Went back to bed in the afternoon and complained of pressure pain in her left shoulder—that evening her husband rubbed her shoulder for a rheumatic pain Pain was not severe, but it felt better with a little pressure or when it was rubbed

Dr McMullen was called in consultation the following day, she still had pains in right lower quadrant, but pain in shoulder had disappeared

On physical examination T P R normal

M M good color

Some tenderness over left shoulder

Heart and lungs, O K.

Breasts, normal

Abdomen, full—pendulous abdomen Some question as to free fluid Some pain in right lower quadrant

Pelvis, normal—except for slight softening of cervix

With this diagnostic history and pain in right shoulder irrespective of a positive physical examination, a diagnosis of ruptured ectopic was made.

Operation revealed abdomen full of blood with ruptured ectopic in middle of right tube

*Conclusion*—1 Pain in neck or acromio clavicular joint is a symptom which is constant after rupture of an intra-abdominal viscus provided the fluid which escapes gravitates up to the diaphragm

2 Fluid in abdomen after rupture very rapidly flows up to diaphragm because patient usually assumes a reclining position

3 The pain is described by patient as a "soreness," "rheumatism," terrible burning pain, pressure pain, "seems to choke off their breathing," griping pain, etc

4 The severity of the pain in the shoulder is directly proportionate to the irritating nature of the fluid

5 Noting the pain in shoulder eradicates that question mark which very often accompanies a diagnosis of ectopic, inasmuch as the patient often has a fatty abdomen and it is often difficult to say positively as to free fluid in the peritoneal cavity

6 Pain in shoulder "per se" is not diagnostic, but it is very helpful in making a positive diagnosis on a questionable case

# INTESTINAL TOXAEMIA CONTROL THROUGH BIO-DIETETIC METHODS

By CLARENCE W LIEB, A M, M D,  
NEW YORK CITY

THE role played by one or more of the "daily half dozen" food sugars, namely, dextrose, maltose, levulose, lactose, dextrin and saccharose, in the causation of many alimentary disorders is fast attracting the attention of leading clinicians and laboratory workers

Civilized man eats a far greater variety and quantity of sugars than the uncivilized man. The ratio of metabolic disease in a nation seems to be in direct proportion to the quantity of carbohydrate food it consumes. The Hebrew race is more prone to certain metabolic disturbances than others and excessive carbohydrate consumption appears to be an important casual factor. The Eskimo lived on a practically one hundred per cent meat diet, in other words, a diet free from sugar and starch, up to the period when food of civilized man was incorporated into their dietary. Stefansson affirms that until then constipation, gastro-intestinal upsets and dental caries were unknown. Since adding cereals and sugar to their diet, however, these conditions are very prevalent, constipation and dental caries being the rule now, rather the exception.

Brown<sup>(1)</sup> has emphasized the part played by carbohydrates in the production of chronic headaches. Holt and Foles<sup>(2)</sup> contend that definite digestive disturbances, chiefly intestinal, may be produced when the carbohydrates in the diet are excessive. They likewise believe that dental caries is largely due to the high proportion of carbohydrate in the modern diet. Jean-Charles, Roux and Griffin<sup>(3)</sup> have shown that insufficient starch and sugar digestion permits considerable carbohydrate material to enter the large intestine. They contend that it there constitutes a culture medium giving rise to organic acids and gases which irritate the intestines and produce symptoms.

Wasserman and Ficken<sup>(4)</sup> have demonstrated that the Frankel bacillus, which is non-pathogenic to man and animals, becomes highly pathogenic to an animal when grown in a two per cent glucose solution. They report results with other organisms in which the

toxicity is increased 30-40 per cent by activation with sugars. They conclude that a similar process of activation, rather than a new bacteriological infection, is the basic factor in intestinal toxæmia.

Barger and Dale<sup>(5)</sup>, Koessler<sup>(6)</sup> and others have demonstrated the production of histamin from histadin by bacterial action in the colon. Patty<sup>(7)</sup> has found HCN in the colon in fairly large amounts. Hendriques<sup>(8)</sup> has shown that acetone can be generated in the intestines bacteriologically. Connellan<sup>(9)</sup> in exhaustive experiments has proved the presence of formic acid in human stools and its bacterial production therein. Lieb<sup>(10)</sup> has repeatedly found oxalic acid in the feces of patients suffering from various disease entities. Shaw<sup>(11)</sup> has recently demonstrated the production of formaldehyde by intestinal bacteria. The toxicity of the above poisons has been definitely proven by different workers, particular attention having been given to histamin both from the laboratory and clinical standpoint. Hence the importance of the scientific control of agents responsible for these toxins is obvious. Experiments now in progress point to the fact that there are other toxic amines and poisons elaborated in the colon which are fundamentally important from the clinical and pathologic standpoint.

The different sugars have been used for a long time in the study and identification of bacteria. The gas and acid reactions and rate of growth on the various sugars are differential points of the greatest value, as the following chart demonstrates.

By inoculating the different sugars with feces with our present method it is possible to determine which are the greatest activators of bacterial growth, this with or without acid production. Sugar solutions so inoculated show different gas or acid production from that found when pure cultures of bacteria are used, as is shown in the appended table. We believe that the resulting picture is more practical with collective inoculation than by preliminary growth and inoculation.

The effects of continued high acidity, whether due to physiologic or biologic processes, is a factor to which gastro-enterologists have given insufficient attention. High gastric, duodenal and cecal acidities in the light of Hammett's<sup>(10)</sup> recent researches must be seriously considered as a cause of intestinal stasis, particularly of the atonic type. This point has been elucidated in the following quotation from Dr Hammett's letter in reply to a question bearing on duodenal research now in progress:

"Continued high acidity in the duodenum would tend to produce a condition of chronic relaxation of this region of the intestine, that is to say the muscular tone of the duodenal portion of the intestine would be lowered. This follows from my results on the effect of changes in Ph on intestinal motility, which results have been confirmed by workers both in this country, England, Scotland and Germany. This flabbiness of tone or relaxation would assuredly result in intestinal stasis, increased gas formation, distension, laggard passing on of intestinal contents in the particular region affected and, of course, indigestion. The further possible harm that might result would be the action of any toxic agents that might be present upon the sensitive mucosa of that part of the intestine where stasis occurred. Here through prolonged contact amounts of toxic substance which under normal conditions might be harmless (relatively) could be conceived of as exerting a deleterious effect by virtue of the time allowed for reaction."

This may seem at variance with the relatively greater number of cases of colonic spasticities elicited by X-ray studies. Spastic conditions in the colon more frequently give rise to symptoms and thus influence patients more often to seek medical advice. In this

way a greater number of such patients come to be roentgenologically studied. The writer is confident, however, that most colonic pathology starts with a condition of atonicity and that spasticity is a secondary factor, the result of inflammatory activity due to irritant substances in the colon.

In order to get a better perspective on the bio-dietetic problem let us consider the behavior of carbohydrates in the alimentary tract. In the mouth food becomes mixed with saliva, a faintly alkaline fluid containing the enzyme, *ptyalin*. *Ptyalin* hydrolyses starch with formation of soluble starch, dextrin, and finally maltose. The next action is that of the gastric juice when the food reaches the stomach which is hardly sufficient to account for the hydrolysis of sucrose without assuming the presence of invertase. The pancreatic juice has an alkalinity corresponding to the acidity of the gastric juice and the one neutralizes the other. The pancreatic juice contains a powerful amylolytic enzyme which hydrolyses starch with production of maltose and, if the pancreatic juice be neutralized, of glucose. Other disaccharides are unaffected, so that though maltose is present both invertase and lactase are absent. All three enzymes are present in the intestinal juice and absorption of the hexoses takes place mainly in the small intestine. By the time food has arrived at the ileocaecal valve practically all of the carbohydrates have been absorbed.

Fructose, mannose and galactose, if slowly introduced into the circulation are converted into glycogen, probably with intermediate formation of glucose. On the other hand, sucrose, lactose and pentoses are not convertible into glycogen. If the percentage of sugar in the blood rises above 0.2, namely, in hyperglycaemia, then sugar appears in the urine. The

"limit of assimilation of carbohydrates" is the amount of carbohydrates that can be ingested and converted into glycogen in the liver without the content of glucose in the hepatic vein (that is, in the systematic circulation) rising materially above the normal, in short, without hyperglycaemia. There is no well-defined limit for starch. It varies enormously for di- and monosaccharides, being from 100 to 250 g., according to the powers of digestion and the hepatic function of the individual.

Recognition must be given to the fact that the sugars as taken in the food do not exist as such on reaching the colon after digestive metamorphosis. This is shown in the following synopsis and is an important guide in the dieto-therapeutic management of colonic patients. Von Lippmann<sup>(13)</sup>

**Starch.** Constitutes over fifty per cent of the solid matter of cereal grains and a larger proportion of the total solids of potatoes, bananas, etc. In processes of digestion (especially when cooked) starch is changed to maltose and the latter to glucose.

**Glucose** (dextrose). Occurs in large amounts in most fruit and plant juices. Almost all carbohydrates yield glucose when split by digestive ferments. It reaches the large intestine as glucose.

**Saccharose** (sucrose-cane sugar). Occurs commonly in the vegetable kingdom. When digested, it is changed into equal parts of glucose and levulose.

**Levulose** (fructose). Occurs with glucose in fruits, honey and plant juices. Reaches large intestine as levulose.

**Maltose.** Occurs in malted or germinated grains. Large amounts formed by digestion of starch by saliva or pancreatic juice and in turn into glucose.

**Lactose** (milk sugar). Occurs in milk. In the intestine lactose is digested into equal parts of glucose and galactose.

It will be seen that the disaccharides and polysaccharides are all reduced to the simple sugars, glucose, levulose and galactose before absorption.

It is to be noted in the above sugar chart that sucrose has the least activating power of all the sugars. It does not, however, reach the colon as sucrose but as glucose and levulose. Abel<sup>(14)</sup> has found that five ounces of sucrose per day fed to healthy men in a mixed diet showed an average digestibility of 98.97 per cent. In gastro-intestinal individuals the absorbability may not keep pace with digestibility and much invert sugar must necessarily reach the colon. Sherman<sup>(15)</sup> states that very little sugar reaches the colon unchanged. The high consumption of cane sugar in this country (nearly 100 pounds per capita yearly) has

great potentiality for physiologic as well as biologic harm. We know that concentrated sugar solutions cause a distinct abstraction of water from the mucous membrane as is noted when a piece of hard candy is held against the cheek for a short time. Invert sugar does not have as deleterious an effect upon digestion as does sucrose. The repeated irritations of the stomach may lead to serious gastric disturbances. Investigations have shown that with too large an ingestion of sugar (120 grams) the emptying time of the stomach is delayed, resulting in lactic, butyric or alcoholic fermentation.

It is an interesting fact that those fruits which we most use for their cathartic action consist mostly of dextrose-glucose, plus levulose: dates, 78 per cent, figs, 74 per cent, prunes, 73 per cent, raisins, 76 per cent. These fruits also contain cellulose which transports the sugar to the lower bowel. The amount of cellulose, however, contained in a couple of ounces of these fruits cannot explain their cathartic action, nor can the amount of their contained acids, nor that of their contained ash, which is less than two per cent in each of the foods. Their cathartic action is due unquestionably to their bacterial activating power in the bowel by their contained sugar. It is a well-known fact that individuals react differently to such so-called laxative foods—the results varying from nil to marked gaseous diarrhea. This latter is without doubt due to furnishing the colon bacteria with an activating medium.

The cooking of fruits and vegetables has a bearing upon intestinal conditions, as it softens the cellulose by changing the intracellular water into steam, thereby rupturing the starch grains as noted in the popping of corn. In this transformation the cellulose and starch are changed into simpler substances as glucose and other sugars by hydrolytic action. These sugars are thereby made more readily absorbable. Hence, thoroughly cooked fruits or vegetables reach the bowel with a minimum of sugar. One reason why some people can take cooked fruits with impunity and cannot take raw fruits without punishment therefrom is due to the above fact, namely, that in the former the sugar is absorbed and in the latter much of it reaches the lower bowel and activates the bacteria which produces gas and toxins, with resulting symptoms. The fact that raw fruits are more laxative than cooked fruits is thus explained, inasmuch as gases and acids stimulate peristalsis. Foods, which produce their laxative effect by their contained sugars may have potentiality for harm. This bio-chemical factor likewise explains the laxative effect of honey, treacle, and marmalade.

The low cellulose diet has been in use for a long time on the assumption that its value lay fundamentally in its non-irritating and easily assimilable qualities. By pureeing vegetables and straining fruits we remove the cellulose sugar carrier and the cellulose factor in producing peristalsis which hastens the sugar toward the colon before the sugars can be thoroughly extracted in the small bowel. Foods rich in cellulose and taken with sugar or starch undergo, on reaching the lower bowel, fermentation with the production of lactic, acetic, formic and oxalic acids<sup>(17)</sup>

The principle of bacterial-activation control was first used by the writer<sup>(18)</sup> in limiting oxalic acid production in the colon as the following extract indicates

"We have been using a dietary containing the minimum amount of cellulose so that as little sugar as possible is mechanically carried into the lower bowel. We believe that the benefits of the smooth diet in colonic diseases are due in large part to a quantitative reduction of activating sugars reaching the lower bowel. A smooth, low cellulose diet mechanically facilitates starch and sugar digestion and likewise lessens peristaltic activity, thereby prolonging the absorptive period. We believe that colonic passivity or immobilization, produced in so far as that is possible by a low or residueless diet, is just as important in curing colonic pathology as is local rest in other conditions such as an infected lung or a broken leg. Doubtless some of the benefits of a starvation cure as due to intestinal rest and an absence of activating sugars in the colon. Chronic intestinal invalids are notoriously improved for the time by barium meals and enemas. It is very probable that intestinal stasis is a protective mechanism, an effort on Nature's part to produce local rest in the presence of inflammation" (Lieb)

Since the publication of the above paper this dietetic principle has been subjected to much experimentation and elaboration.

It has been demonstrated through laboratory study and trial and error methods that very careful individualization of this dietetic principle is indicated.

The digestive capacity of the different digestive organs and their enzymes must be considered. Neither in the beginning or end of treatment must the change from dietetic control or dietetic release be made too abruptly for there are physiological as well as biological principles at stake. A low residue carbohydrate diet, sufficient to maintain body weight in about ten per cent of patients, produces considerable digestive turmoil. Even though 50 grams of proteid are added to this diet the symptoms do not entirely disappear.

If these patients are placed upon a low residue, thoroughly cooked proteid diet all symptoms disappear and the bio-dietetic problem becomes a simple one.

Sugars taken in liquid form (in beverages) are practically all absorbed before they reach the large bowel and therefore do not have to be considered if within the digestive capacity and not taken with cellulose containing food.

The sugar taken in the form of candy does not enter into the bio-dietetic problem unless eaten in large amounts or with food containing such residue. Agar-agar undoubtedly carries much sugar to the lower bowel. Part of the action of the agar-agar may be due to its power of carrying sugar to the lower bowel and there stimulating peristalsis by gas and acids which have been produced by fermentation.

There are very few dietetic schemes which should be followed intensively for more than two or three weeks. We must guard against avitaminosis, proteid fat, and carbohydrate over dosage. The success of many of the vaunted dietetic schemes lies in their common denominator, a low residue content. Is it not possible that colonic sugar control has been the therapeutic factor?

No therapeutic regimen, dietetic or otherwise, is a rational one without a complete gastro-intestinal survey to eliminate the possibility of mechanical factors or morbid pathology. The problem is an alimentary one, not intestinal alone. Abel<sup>19</sup> has shown that histamin increases gastric acidity. Hyperacidity we know decreases pancreatic function. With decreased pancreatic function we have to deal with an intricate metabolic problem. Poor starch and sugar digestion linked up with the hyperperistalsis so often met with in hyperchlorhydria results in a great increase of activating sugars in the colon with a consequent increase in histamin and other toxins, thus producing a vicious circle.

An interesting observation made repeatedly on gastro-intestinal invalids was the frequent hyperglycemia with rapid amelioration of symptoms when insulin was used in conjunction with saccharo-dietetic control. Naturally it would be hard to draw conclusions from such observations without repeated control experiments. An acceleration in symptomatic cure seemed to take place with insulin therapy even in the presence of a normal blood sugar.

The writer has worked out four dietetic procedures for the selective individualization of each patient.

It would seem on first analysis that the best way to solve the sugar problem as above elaborated should be to omit all foods containing the contra-indicated sugars. But this has been shown to be impractical since the foods which contain the most sugars have in general the least residue and since intestinal immobilization and improved

nutrition are also fundamental factors in treatment, such a scheme is impractical. Therefore, our problem resolves itself to the limitation of colonic sugars through the following methods.

*Diet No 1 Residueless* (practically), containing fresh butter, cod liver oil, sugars, gelatin, calcium, raw vegetables and fruit juices and lactalbumen (as best tryptophan source).

Indicated in severe ulcerative and advanced cases of mucous colitis and to replace the starvation treatment of epilepsy where an intestinal intoxication as an etiological factor is suspected.

*Diet No 2 Low Residue* This diet contains the low cellulose vegetables and fruits, non-fibrous, tender and well cooked fresh animal foods, no milk, but the liberal use of heavy cream, butter and oil. Sugar may be used in tea or coffee.

Indicated in the treatment of the average case of intestinal toxæmia. Hypochlorhydric cases do well on this diet, hyperchlorhydric cases may develop considerable gas due to inhibited carbohydrate digestion, but alkaline therapy or oral pancreatic glandular therapy eliminates this tendency.

*Diet No 3 Low Residue Breakfast and Luncheon* (as in Diet No 2), *High Residue Dinner*. High cellulose vegetables, non-fibrous, well-cooked fresh animal food, diabetic breads, no desserts (practically a diabetic meal).

Indicated during the post-intensive treatment of intestinal toxæmia and in cases complicated with intestinal atony.

*Diet No 4 Intensive High Protein Diet* (sugar free). As near to a 100 per cent meat diet as possible. Animal fats given liberally. Meat should be tender, thoroughly broiled, baked, boiled or stewed.

Indicated in colonic toxæmia in which saccharolytic organisms such as aerogenous capsulatus predominate and where renal function is unimpaired. (Menus published in reprints).

The writer's studies on the value of a sugar-free, proteid diet combined with the results of the interesting dietetic observations made by Stefansson, the noted explorer, during his many years in the far North have amply demonstrated the advantages of a meat diet, properly adapted, in the control of certain types of intestinal toxæmia. But the therapeutic principle underlying a meat dietary appears to be a matter of controlling, qualitatively and quantitatively, the carbohydrate percentages of the colonic fecal content. Doubtless the success of Dr. Salisbury's meat therapy was due to carbohydrate control. On the meat diet as elaborated by the writer a balanced diet can easily be given. Carbohydrates can be given in liquid form in strained fruit juices. Fats can be given during meals in any quantity desired. A very interesting fact was told by Stefansson bearing on this subject to the effect that an exclusive meat diet without fat resulted in great

bodily and digestive suffering which was always quickly corrected by the addition of fat, even though rancid. The innocuousness and undoubted merit of a 100 per cent meat diet and the substitution value of fats for carbohydrates is hereby beautifully shown on a large scale. Stefansson's dietetic observations are worthy of very careful scientific consideration.

It has been claimed that bacterial flora can be changed at will by merely changing the diet from a starch to a proteolytic one and vice versa. Is it not possible that the bacterial picture in such findings is dependent upon the quality and quantity of the various sugars reaching the colon? Certainly the feeding of dextrin and lactose has a definite rationale. But in the opinion of the writer the mere changing of the bacterial flora is not conducive to the best clinical results without the assurance of a thorough colonization of the large bowel with *B. coli*.

Gratifying results have been obtained in the treatment of migraine, petit mal and epilepsy with a 100 per cent meat diet and laboratory experiments are under way to illuminate our clinical observations. Stefansson relates the interesting case of an epileptic whose symptoms entirely disappeared directly he was forced to subsist on nothing but meat while in the far North.

The treatment of the frequent constipation or occasional diarrhea associated with intestinal intoxications requires anatomic, physiologic and biologic knowledge of each case. It is here that the intelligent application of both the art and science of medicine finds its greatest therapeutic opportunity. A complete gastro-intestinal survey of every patient is therefore indicated. The X-ray and the proctoscope give us invaluable information and without these observations neither pill nor diet should ever be prescribed. At the extremities of the colon lie the appendix and the sphincter, each of which may, under pathologic conditions, produce colonic disfunction. Between these two points may be diverticula, kinks, segmental or generalized atony, etc., any of which may have been induced originally by an intestinal toxæmia. It is unreasonable to assume that bio-dietetic methods alone can cure these morbid states, yet it is almost as unreasonable to suppose that these can be cured by radical methods without bio-dietetic control.

Constipation does not necessarily spell intestinal toxæmia. An apparently normal state of health for a varying period of time is possible in many cases of obstinate constipation. It would seem that many individuals have established an immunity against a gradually developing toxæmia or at least that their detoxicating mechanisms are unusually efficient. But if stasis continues too long pathological changes ensue with their attending evils.

No case of intestinal toxæmia can be cured by

catharsis or with intestinal antiseptics per se, whether orally or anally administered. It is about time that this scientifically known fact found general acceptance among all members of the profession. The regular taking of cathartics sooner or later collects its toll of bodily and mental vigor. The physiological and secretory unbalance thus induced, the high cecal acidity engendered, the colonic unrest thereby instituted when colonic immobilization is indicated, the false sense of intestinal security or normalcy which daily catharsis gives—all tend to hasten the day of gastro-intestinal invalidism with all its physical and mental suffering.

We are confident that there are but few cases of intestinal toxæmia and aberrant intestinal motilities which cannot be cured by the proper application of scientific therapy of which bi-dietetic carbohydrate control appears to be a basic factor.

NOTE The writer wishes to express his sincere appreciation of the valuable assistance rendered him by J J Connellan in the preparation of this paper

### PSYCHIATRY IN RELATION TO THE PUBLIC SCHOOLS \*

By A. B SIEWERS, M D,

SYRACUSE N Y

**A** FEW years ago the Public School System was composed, roughly speaking, of Teachers and Principals, with a Superintendent. Health of the children attending school did not constitute a part of the Educational Work. The Child's health, however, was realized to be important, and gradually medical activity was introduced. This medical activity was chiefly directed at contagious diseases, and soon became a great power in Community Hygiene, especially as "Preventive Medicine." For some years now the medical work in the schools has been directed toward these factors, in which the results can be clearly seen. That is, attendance records have shown marked improvement under the influence of "Preventive Medicine."

Psychiatry lags behind the field throughout medicine. Psychiatric knowledge does not become part of the general medical knowledge, nearly so quickly as does knowledge in other aspects of medicine. Preventive medicine in the field of Psychiatry has not been advanced in a way at all comparable with that in other fields. Among the reasons for this are possibly

- 1 The inability to show results
- 2 The fact that Psychiatrists are consulted as a last resort in cases of "Nervousness"

Physicians would be severely criticized if they

neglected the surgical aspects of an acute appendicitis, yet they can with impunity neglect the psychiatric aspect of disorders in behavior or backwardness in class rooms. Psychiatry is probably at fault to a large extent in that it functioned so long as a "relegator" of the worst cases to institutions or special classes. Of course today the School System has ungraded classes and classes for backward children but Psychiatry is not contributing enough in a "preventive" way.

There is a noticeable lack of Psychiatric Work in many communities. In Syracuse for example, there is only one member of the Medical Staff of the Department of Education devoting time to Psychiatry. There are no official provisions for anything except the most cursory mental examinations.

There are only three classes in the whole city for atypical children, and the enrollment of the three combined is less than fifty. Two of these classes, one for Boys, and one for Girls, are in an abandoned school building, and the third, for Boys, is in a building likewise abandoned, except for overflow from a nearby school, and a special class in sight saving.

Some of the larger schools have ungraded classes, but this is the exception rather than the rule. Each school has its quota of feeble minded, backward and Psychopathic children, about whom mainly nothing is done.

\* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester, April 22 1924

The necessity for "Psychiatric" work then can easily be seen, and we are brought face to face with the question, "What can be done?" The provision of additional special classes would probably be admitted as necessary without argument. Probably every school has enough children who do not get along with the regular curriculum to warrant a special course of study. This plan would handle only the backward child who is not a problem from point of view of behavior. The Psychopathic children, however, who are behavior problems, the quasi-delinquent, and the school children who are more or less constantly appearing in the Juvenile Court are "Behavior Problems," and they are the ones who require special study. In this study, the co-operation of Doctors, both in and out of the school system, and the laity, with the Psychiatrist or Mental Clinic conducting the study, is absolutely necessary. This co-operation involves referring all behavior problems to the Clinic as soon as they are recognized. What usually happens is as follows:

Any abnormal behavior on the part of a School Child is at first punished. Later on should the child repeat the offense, the punishment will be deemed inadequate and made more severe. Failure of this added severity to bring about the desired correction might then call forth some effort at determining the real difficulty, but by this time the child is labeled as a "bad one," and might have by this time developed an attitude of suspicion and antagonism which makes the problem all the more difficult.

Psychopathology in the adult is often in the nature of the end result of a long process and the naturalness of the disorder is not so apparent as in the child. The child has to be considered Psychobiologically, that is, from the point of view of the individual as a physical and social unit. We must not divide the child into stomach, heart, brain, etc., without consideration of the personality as a whole. Somatic complaints may be merely a way of expressing a problem of the personality and may be a means by which the patient consciously or unconsciously hopes to achieve a better adjustment.

Tantrums in children, or the substituted phenomena, such as vomiting, headache, convulsive manifestations, anxiety states, obsessive thinking and doing, or the more socially significant delinquencies, such as stealing, lying or running away, all call for a study of the child in relation to the demands of his environment, for often these manifestations are likely to be considered a part of a child's heredity, when as a matter of fact, an attempt to adapt to the environment is the real cause.

*Name*—Donald G——, age 10, is a very difficult school problem, as he teases and quarrels with all the younger children. The result of the

home investigation in January of this year is as follows (*Sources of Information*—Mother, paternal aunt, brother Cedric, school nurse, school teacher, and principal).

*Family History*—*Father*, age 47, chronic alcoholic, irregular work history. Formerly worked in paper mills, now unemployed, trying to find tailor work. His sister says "There is no reason why he should drink, he was well brought up. His father never even smoked, and he was brought up to obey and to do what his mother told him to do." When he is under the influence of liquor he is irritable and ugly, but has never become abusive.

*Mother*, age 40, crippled 7 years ago with infantile paralysis. Is able to get around the house on crutches and do her housework, but can not go up and down stairs, and has been out of the house only twice in a year. She admits she is excitable and irritable. Seems to be fairly well adjusted to her crippled condition and does not indulge in self pity. Gives the impression that she would lack in firmness in handling the child.

*Siblings*, *Gilbert*, age 21, working and living at home. *Sybil*, age 19, telegraph operator. Has left home and is working in Florida—"She wanted to see the world, so she went south with a girl friend."

*Cedric*, age 17, working in Western Union, and planning to be a telegraph operator. Earns \$17 a week. His mother says "He's got just as bad a temper as Donald has and gets just as mad when he can't have his way."

*Donald*, age 10, patient.

*Beverly*, age a year and a half. Cesarean birth. Mother had been crippled for five years. Child appears well.

*Home Condition*—The G——s formerly lived in Fulton, moving to Syracuse about a year ago, because Mr G—— could not get work in Fulton. They live in a poor neighborhood, where the foreigners are of a much better type than the low white population. House of ill repute, etc., are in the near neighborhood, if not in that very block. The family live in a two-story house, rent \$35. The family life is not apparently a happy one. Donald says "My father's horrid when he's drunk. Last night he was so drunk he couldn't stand up. He had spent all his week's pay except \$2, and my mother, she took that from him. My mother cries, but he can't hurt her or my brothers. They just hit him back and my sister does too." "Cedric's the worst to me. He teases me." Mrs G—— bore this out by saying that Cedric had been very bright in school and he always mocks Donald for his difficulties in school.

*Personal History*—Born April 16, 1923. Prolonged labor, no instruments. Mother states that her husband was drinking very heavily at the period of conception—"was drunk most of the time." Developmental history apparently nor-

mal Walked at one year, talked at a year and a half—but he was never as bright as the other children in learning to talk” No history of convulsions Cholera infantum from six to nine months Measles and mumps, no serious after effect

*Habits*—No history of bed wetting No history of masturbation Goes to bed early, sleeps well, no nightmares Good appetite

*Recreation*—Donald does not go with a “gang” He says “there are no nice boys on that street The big fellows all pick on me I wouldn’t go to the Boys’ Club because the big boys there all hit you I went to the Y M C A last summer but the fellows hit me there, and I won’t go back there to swim again No, I don’t play baseball, the fellows won’t let me” On his return from school, Donald wheels the baby out in her cart, as his mother can’t take the child out and there is no back porch for the baby to stay on He runs all his mother’s errands, buys all her supplies and brings her back the correct change “I don’t know how I could get along without Donald, there is no one else to do things for me” Sometimes he stops and plays in the streets instead of coming from school and taking the baby out Donald says that he doesn’t mind taking the baby out—“Crossing the street with the baby carriage is the worst, that’s all I mind”

*School History*—Donald attended the Erie Street School in Fulton until October, 1922 His mother claims he had no difficulty in this school except in the matter of passing the grade “He repeated the 11 and 12, two times I used to think he would never get out of the First Grade, but no one ever told me he misbehaved in any way” When Donald began Putnam School, he was put in 12, and has been advanced each term The principal realizes that he should have been advanced to a class with older boys, but it was impossible to do so, as the child was not capable of doing higher grade work Donald has been a constant conduct problem since his arrival He constantly hits, slaps, teases younger children He is only good when he is running errands He is trusted with money and has never been known to steal He keeps his class constantly in an uproar by annoying the other children, always younger than himself When crossed, he has outbursts of temper, stamping his feet or lying down on the floor, kicking his feet and screaming Mr Wright tells a story where he punished Donald for slapping other children He gave him his hat and coat and told him to go home A few minutes later he looked out of the window and saw Donald lying on the sidewalk crying and kicking his feet in the air He brought him back to his office and kept the child the rest of the day His last episode in school, he threw a marble at a boy, hitting his glass and nearly putting his eye out Mr Wright says he scolded

the other boy for being where he should not have been, but Donald’s only reaction to the episode is that they didn’t let him explain that the other fellow had put him in an ash can This is denied by other children who were witnesses of the fight Mr W—— told Donald to go back to the class, saw him enter the room, stamping his feet and then, seeing a pencil on the floor belonging to a little girl, began to kick it all over the floor Mr Wright then brought him to his office and the child cried and cried and could not be quieted

Donald likes the first teacher whom he had, Miss Dickerson, and feels that she was just and kind to him Miss D—— says she was fond of the child but that he was the most difficult boy she ever had to handle and she was always in terror for fear he would hurt the other children His present teacher is an older woman, who has taught for 37 years, and Mr Wright seems to feel that Donald is too much for her

Any measures which can be introduced to help Psychopathic Children adjust themselves in the community in which they live and in attendance at the school which they should attend, would certainly be infinitely better than placing them in Reform Schools and the like

There are no Special Classes in this school, but there is a class for ungraded boys who need individual attention to get them up to grade Donald was put in this class and the situation was gone over with the mother whose cooperation, to a certain extent, was obtained These simple measures have not produced an angel, but Donald is no longer the “behavior” problem that he was

Troublesome children are present in every school To group such children would certainly create a tempest and would not help The necessity which stands out in the study of the psychopathic child, and likewise, in an attempt to help the child, involves not only a study of the child’s behavior in the classroom, and on the playground, but also a study of the child in the home There must be a connecting link between the environments in which the child lives, the school on one hand, and the home on the other This cannot be done by teachers who have not had special training The idea of a visiting teacher to see the child in his home is a good one, but it cannot be carried out by the teachers who have long been at work under the old system, and have very definite convictions as to the relation of the teacher to the child

A “Child’s Study Department,” such as the Rochester public schools have, is an example of active psychiatric work The principals involved would well be put to use by other communities

This is really an Advisory Department to which principals, teachers, parents and social workers can come for help to better understand children, besides it is a Bureau of Child Standards

The staff consists of Director, psychologist, psychiatrist, neurologist, four psychological examiners, one medical examiner and one home visitor. The problems presented are Backwardness in one or all subjects, superior work in

several or all subjects and irregularity in attendance or behavior.

The recommendations are directed at a correction of physical defects and social and educational readjustment. The value of this work can hardly be overestimated.

## MEDICAL SERVICE PROBLEM

From the Standpoint of a Rural Physician

By LAWRENCE E. SPROUT, M.D.,

WEST LEYDEN, N. Y.

Service to a rural population requires mode of travel, for 80 per cent of the work of the physician in the country is home service. Therefore a map of the section to be served, with location of farms, camps and smaller villages and road conditions in all seasons of the year, gives us an idea of troubles to come.

The problem seems to be for the most part seasonal. With automobiles and improved roads, the hospitals are easily accessible and the doctor can reach his patients with very little inconvenience and have some time for recreation. Winter and Spring is a very different matter. The doctor in these seasons must spend most of his time on the road and this calls for endurance.

To the country people, we, the doctors, are servants of the public and *must* serve. We never tire and should be waiting to go at once for each and every one. Anybody with the title of "Doctor" means the same to them. A school is a school. No attempt is made to learn whether the medical training is good, and he is taken in or moves on as he appeals to the people as a "good fellow."

The work of the country doctor is mostly curative. The Health Officer is supposed to do all that is necessary in the way of preventive medicine. The rural physician has no time for anything except the sick.

### QUALIFICATIONS FOR RURAL SERVICE

The doctor, to do country work, must necessarily be physically fit to stand the long, tiresome trips in Winter and do a large part as chauffeur and hostler. His scientific preparation must also be general—a specialist in every department of medicine. Mostly he works alone with very limited equipment.

Perhaps above all else should come the living conditions in the country. We can now equip a home in the rural community with all the comforts of the city—but this expense must necessarily be met by the community unless the doctor can see a permanent location. The social side must also be considered and will depend upon the doctor's family as well as upon the people of the community, for the term of service will depend upon the attitude of the doctor's family toward the country.

### HOW AND WHERE SHALL WE GIVE SERVICE? AND WHAT SERVICE SHALL WE GIVE?

This problem can and should be met by the doctor that has studied conditions and will work to improve them. A man from the country or one having boyhood knowledge of country life can perhaps get along better and do more toward the education of his rural patients. Many of the problems of rural practice are solved outside of the practice of medicine, or at least without the pill case. The attitude of the patient many miles from the doctor, with roads almost impassable and storm raging, is far different from that of the patient easily accessible to the doctor. The former usually thinks, "Will he try to come if I get worse?" "Could he get here?" The telephone is on the wall, so the doctor gets the call and makes a trip which is perhaps unnecessary.

The Medical Service Problem must be solved in many ways. First of all, by the education of the rural population, which is changing rapidly in some sections. The Department of Education, with examination of school children and remedying defects, will help to take into homes some idea of preventive medicine. The Nurse, County or Community, by her work with children, the Department of Health Clinics (pre-natal, pre-school and dental), Mothers' Clubs, Health Automobile and Radio Health Talks, reach districts that are inaccessible in Winter.

When the rural communities feel the need and will work and invest money and supply a house for the doctor, and also provide in some way a few rooms that may be used by the country people as a hospital, and the people can be induced to use such a place so that the work may be somewhat centralized, then the demand for service can be met and that service will be received at home. These conditions will support a doctor and prevent the work from drifting in Summer to the cities.

The medical profession has a great duty to perform. A bit of introspection is first needed, then co-operation. If the profession could work together as a unit and by a "Gentlemen's agreement" eliminate to some extent the competition which means so little in the country, we could follow the work of the clinics and more profitably and easily remedy defects found.

## SPOKESMEN FOR THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Who is authorized to speak in the name of the Medical Society of the State of New York?

The supreme source of power in the Society is the House of Delegates, which corresponds to the House of Commons of England. It is composed of 172 members of whom 150 are elected by the component county medical societies, and 22 are the elected officers of the District Society, the Chairmen of the Standing Committees and the Presidents of the District few minutes. The House of Delegates makes the laws and by-laws of the Society, enacting his feet and formulates the policies of to his office and meets regularly once a year day. His last episode reports of the officers marble at a boy, hitting society and to author-putting his eye out. Mr Wright

ize the activities of the Society during the coming year

The Council of the State Medical Society is the executive and administrative body of the Society. It is composed of the twenty-two members of the House of Delegates who are officers of the State Medical Society. It is empowered to act in the name of the Society when the House of Delegates is not in session. It holds three regular meetings annually and may hold more after legal calls.

The Council has an executive committee of seven members to whom many of the powers of the Council are delegated and who have charge of the administration and business

affairs of the Society while the Council is not in session

There are five standing committees of the State Society, each of which has certain executive duties to perform. Special committees are also frequently appointed by the House of Delegates, the Council, or the Executive Committee, to whom specific activities may be assigned.

It will therefore be seen that there are at least five groups who are authorized to speak in the name of the Medical Society of the State of New York, but their authority varies to a great degree, from almost the unlimited power of the House of Delegates to the modified power of the Executive Committee. There is, however, a system of referendum voting which strengthens the authority of the body ordering the vote.

1 The House of Delegates may order a referendum vote of all the members of the State Society. This vote may truthfully be said to represent the attitude of the Medical Society of the State of New York to a complete degree.

2 The Council may order a referendum vote of the members of the House of Delegates.

3 The Executive Committee may order a referendum vote of the members of the Council.

The referendum vote of the House of Delegates, or of the Council, may also be said to express the attitude of the Medical Society of the State of New York.

The chairmen of the standing committees may properly be credited with the prerogative of speaking for the Medical Society of the State of New York along the lines laid down in the constitution and by-laws, but outside of those specific lines, they cannot act as spokesmen for the State Society unless their reports are approved by the House of Delegates or the Council.

A special committee must have its report approved by the appointing body before its members can claim that they are spokesmen

for the Medical Society of the State of New York.

The most striking application of the principles of spokespersonship is afforded by the Chairman of the Committee on Legislation in his dealing with the Legislature. When he appears before a legislative committee either favoring or opposing a bill, it is necessary that he be in a position to say that he represents the physicians of New York State, and is their spokesman. He ascertains the attitude of physician by correspondence and consultations with the Chairmen of the Legislative committees of the County Medical Societies. These chairmen are in close touch with the members of their County societies and can ascertain their attitudes with a considerable degree of accuracy. The Chairman of the Committee on Legislation therefore has unofficial sanction to act as spokesman for the physicians of New York State without securing the sanction of the Council or the House of Delegates. However, in matters of controversy in which there is a division of opinion, the Council has taken a referendum vote of the House of Delegates, as was done in regard to supporting the Practice of Medicine Bill by a vote which was completed on the fifth of March.

When the Chairman of the Committee on Legislation takes a certain attitude on a bill, he is greatly embarrassed if a member or group of members take an opposing attitude without consulting or informing him. Any physician or county society has a right to express dissent from the opinion of the Chairman, but that opinion should come first to the Chairman of the Committee on Legislation to be presented as a minority report. To express disapproval openly and without due warning gives the legislators the impression that the medical profession is divided and without influence in the community.

It is well that members of the Medical Society of the State of New York consider the responsibility that is upon him who claims to be the spokesman for the medical profession.

---

## ACTIVITIES OF THE JOURNAL

This Journal reflects the activities of the Medical Society of the State of New York, and tries to give the reader up-to-date information regarding every phase of the work of the society.

By far the most important activity since January 1, 1925, has been medical legislation. The Journal has listed something over seventy-five bills which affect physicians, and the practice of medicine, and has been the medium of

communication between the chairman of the Committee on Legislation and the members of the State Medical Society. We feel that this work has been done better than ever before and that the results have justified the effort.

Our only regret is that we have necessarily put less stress than usual on the ordinary activities of the society and have neglected some departments of the Journal. The omission of the page of Prunes has probably given rise to

the greatest number of complaints regarding our short-comings, but we are also reminded that our editorial pages lack variety of subject and breadth of view since we have confined ourselves too closely to legislative matters.

We share the feelings of our critical friends and regret the unbalance resulting from the prolonged legislative activity. But the adjournment of the Legislature is in sight and we will resume the publication of a broader field of medical topics.

We are anxious to resume the Medical Surveys, and our impatience is still further excited by an appreciation which was published in the February issue of the Bulletin of the American Medical Association. After a page of quotation from our survey of Clinton County the article concludes:

"All of the surveys have produced compilations of valuable information that the Medical Society of the State of New York should have, and can use to fine advantage. Any State Medical Society can easily do what is being done in New York State to its own advantage, to the benefit of its county societies and for the public good. Facts in hand are valuable."

The Committee on Publication has authorized us to continue the surveys, and we keenly anticipate the pleasure of making and renewing acquaintances among the physicians throughout the State and assisting them to evaluate their own work in their home communities.

Doubtless our medical friends have noticed a new department which has flourished despite

crowding by legislative matters. We have reported the activities of the Medical Society of the County of New York in its work in Periodical Health Examinations. New York County has undertaken the work along lines differing from those adopted in Kings County. A special feature of the New York plan has been a series of sixteen lectures on various conditions which might be found in making an examination of a patient. The word pre-clinical has been stressed in its application to conditions when they are in a stage which is incipient and curable. We have made abstracts of nine of the lectures and published them in the news columns of the Journal, and expect to publish abstracts of the others.

We are gratified that there is a call for more scientific articles. We had wondered if physicians get all their medical literature out of periodicals devoted to the specialties, but we recall that the great majority of members of the Medical Society of the State of New York are family doctors who get their medical articles principally from such general periodicals as the New York State Journal of Medicine and the Journal of the American Medical Association.

We shall be only too pleased to gratify the desires of our readers for short practical articles on the recognition and care of common diseases. We will probably have more to say along these lines in the future. In the meantime, send your suggestions regarding the articles which you wish to see published.

F O

## CONFERENCE OF CHAIRMEN OF COUNTY LEGISLATIVE COMMITTEES

We are hearing favorable comments on the happy idea of bringing together the chairmen of the County Legislative Committees for a conference regarding the medical bills before the Legislature. A logical program of considerable extent had been prepared by the chairman of the Committee on Legislation, and there was no lost motion during the three hours that the conference lasted. The discussions were as snappy as the printed program, and those in attendance learned the points of view of the others.

A social dinner after the conference gave an opportunity for any member who was impatient or aggrieved to come to an understanding with his opponent.

Such a conference is an ideal way of securing unity of action and interest in the activities of the State Society. We have heard the suggestion made that the chairmen of other Standing Committees might with profit organize similar conferences with representatives of the constituent County Medical Societies.

F O

# LEGAL

By GEORGE W. WHITESIDE, Esq  
Counsel, Medical Society of the State of New York

## THE MISSION OF ORGANIZED MEDICINE TODAY

We have seen in the past twenty-five years horse cars and carriages give way to motor-driven vehicles, old landmarks have been torn down and in their places have been erected massive structures of steel and stone. The skyline of the city now visualizes a change that seems magical and inspiring, aeroplanes and dirigibles are no longer a novelty, and the radio registers the most recent, but probably the sharpest, contrast of the present day with the past.

The contrast in the procedures and practice of medical science during this same period shows as startling and radical a change. A work on surgery that is ten years old is practically useless, as the strides of progress in that science have in so short a time carried the art so far. In diagnosis the trained eye, ear and touch of the skilled physician are supplemented and aided by the X-ray, the laboratory where delicate tests are determined, and improved apparatus that gives precision and accuracy in the measurement of the bodily functions. The psychologist analyzes the changes in abnormal mental conditions by his comprehension of the subtle influences that disturb mental balance and manifest themselves in abnormal physical and mental reactions. The changes about us that so readily register upon our minds are no more startling than those which the science of medicine have undergone in these recent years.

The passage of workmen's compensation laws throughout the country has brought the medical profession into close contact with the industrial world and has produced changes in the practice of industrial medicine that are short of revolutionary. The tendency to mesh the medical profession into the industrial machine and make it a cog in the mechanism, gained sufficient momentum a few years ago to make the passage of compulsory health insurance laws a serious menace to the profession's independence. This effort, however, was but a symptom which sounded the warning of how the industrial world contemplated dealing with the medical profession and of the design to lock-step it in obedience to purely materialistic and industrial needs. The profession was saved from this impending doom not so much by the loud protest of its individuals, as by the power of its organized intelligence. New importance was given by the compulsory health insurance campaign to the necessity and value of organization in medicine, in order that

the profession might take its proper place in the civilization of this present industrial age and not become a part of the army of white-collared wage-earners. That battle has been won, but have the gains of the victory been sufficiently consolidated for a further advance by the profession?

Possession of intelligence alone is not sufficient to cope with the present day problems of this industrial age—for the professors of the schools and colleges throughout the country possess a learning and intelligence quite comparable with that had by any of the learned professions, but their economic status has been one of pity. Their position in the life of this material age is not adequately registered and organized, because such profession does not adequately function in the organization of its intelligence and the expression of its congregated judgment and power.

Numerically the medical profession are practically negligible. Their total voting strength throughout the United States is less than that of a few blocks of tenement dwellers in the City of New York. The structure of ignorance, of blind political partisanship, of selfish greed, will give way to the power of organized intelligence as readily as the giant steel structure can be made to crumble and fall by the application of the acetylene torch.

The industrial world depends upon the physician to keep the workers healthy and to treat scientifically industrial injuries and diseases. Industry must rely upon the maintenance of a high degree of professional integrity, learning, skill and morale in the medical profession to maintain a high standard of industrial production.

The great life insurance companies that have outstanding today fifty-four billion dollars in policies of life insurance have based the writing of every dollar of their promise to pay those billions of dollars upon the opinion, the skill and the integrity of medical men. The millions of dollars paid annually in health and accident insurance are paid only after a medical man has made his examination and given his opinion. The workmen's compensation for industrial accidents, unknown twenty-five years ago, represents today an investment of millions of dollars and the payment of one hundred and seventy-five million dollars in premiums a year. Of these premiums twenty-five million dollars a year are spent for medical service. The whole purpose of this law would be defeated and its

operation ineffective were it not for the contribution made by the medical man in the performance of medical services under its provisions. The banking interests of the country are closely allied with these various industrial and insurance corporations and depend largely for their money upon the millions of dollars that flow into their treasuries. The entire economic system, therefore, has a direct dependence upon the maintenance of a high degree of learning, skill and integrity of the medical profession.

The laws that destroy the profession's morale, by permitting the influx of hordes of ignorant and unqualified to practice a branch of the healing art and exploit a theory of treatment contrary to the science upon which disease today is treated, and laws that destroy the initiative of the medical man in the pursuit of science and in the acquiring of economic independence, strike not

only at the medical profession but through it at the great industrial and business enterprises of this present age.

These are the changes that the last quarter of a century have wrought—quite as amazing as any that we so readily visualize and comprehend about us. Their lesson, it seems, is to emphasize the imperative necessity of firm organization of medical men so that organized intelligence can combat the destructive effects of the industrial tide and guide it into channels of usefulness to mankind and of progress for the race. In this work in the State of New York the Medical Society of the State of New York and its constituent county societies should have the support, not of passive acquiescence, but of active, militant aggressiveness of every medical man of the State, and its leaders should be encouraged and supported in the carrying out of its great mission.

### PROLAPSED UTERUS

The complaint in this action charged that the plaintiff, a woman, consulted the defendant to cure her of the malady from which she then suffered, that the defendant was careless and negligent in his treatment, operation and prescribing for the plaintiff and that as a result of the same the plaintiff was greatly injured in her health and constitution and required to expend moneys for further medical care and attention.

In this action, it appears that on May 6 the plaintiff called at the defendant's office complaining of irregular menstruation and pains in the region of the genital organs. Upon a digital vaginal examination he found that she was suffering from a prolapsed uterus, and advised the performance of a curettage. A general physical examination of the patient was negative. In the endeavor to correct the prolapsed uterus he inserted a hard rubber ring pessary. He continued to treat her daily for a period of ten days. On the second or third day after the insertion of the pessary, upon examination he found that the

same was missing. The patient had not found the pessary. After the first ten days he treated her every other day for a week. During the period that he attended the plaintiff his treatment consisted of the application of douches of lysol solution. He also prescribed an opiate for her nervous condition. The patient was not seen again by the defendant until the following August when she returned complaining of pain in her right leg between the thigh and the knee. Upon examination he diagnosed her condition as neuralgia or sciatica and prescribed salicylic acid. At this time she was seen only once and since then had not been seen by the defendant. Upon the visit in August no vaginal examination was made nor any complaint made by the plaintiff of her previous treatment.

When this action came on for trial it was abandoned by the plaintiff's attorney and the complaint was dismissed for failure of the plaintiff to prosecute.

## BRIEFS ON BILLS

### BRIEF SUBMITTED IN BEHALF OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK TO THE ASSEMBLY COMMITTEE ON LABOR AND INDUSTRIES IN FAVOR OF ASSEMBLY BILL INTRODUCTORY 1351

The Medical Society of the State of New York begs leave to offer its commendation and urge the passage of the above bill, which from consultation with members of the medical profession—not all of whom are members of the Society in this State—seems to meet a situation that has been a cause of acrimonious discussion on all sides relative to the supervision, care and treatment of injured employees of this State under the industrial laws

The Medical Society of the State of New York maintains that the proper ones to advise concerning the supervision, treatment and care of injured employees should rest primarily and in large measure with some organized and recognized group of physicians, and this bill seems to approach that thought the nearest of anything that has yet been offered

In the formative period of the Compensation Laws no well directed effort was made for seeking the advice of such a group, but individual physicians were consulted, many of whose recommendations were biased from the standpoints of personal aggrandizement, from too great favoritism toward injured employees or from a desire to placate employers or insurance companies as individual groups

Following the first draft of the Compensation Law a committee was appointed on which there sat several members suggested by this Society and other groups, and at hearings held throughout the State these medical men collated facts concerning the care and treatment and handling of injured employees

Recommendations were then made to the major committee on the part of the medical representatives, but it is a sorrowful thing to record that these recommendations were in the main ignored

The Medical Society of the State of New York has sought year in and year out to have legislation passed which would provide free choice of medical or surgical attendance for an injured employee, but it has consistently failed in this regard

It recognizes that there are physicians incompetent to treat certain types of injuries which these same physicians have attempted to do, to the detriment of the standing of the medical profession and to the permanent injury of the employee to a greater or lesser degree, as well as in other instances inflicting undue financial burden upon the employer and the insurance companies, but this question would be met undoubtedly by sitting in judgment in the County

Society groups of physicians upon the question, and with the help and advice of a co-operative and real medical director, incompetent physicians would be discovered and their limitations outlined to the satisfaction of all

It is to be hoped that the reading of subsection 5 of Section 81, should this bill be passed, could be so construed as to furnish thought and action to the medical director or his examining physicians that this phase of the problem might be overcome

It is also to be realized that a medical director is more familiar with the charges for medical and surgical attendance or treatment and for nursing and hospital service in the various communities of the State than would a lay person be so acquainted, and his being suggested by this large body of physicians will make him in a measure beholden to the entire group of physicians in the State, to the extent that the discussions as to his competency or management of medical procedure will be brought up from year to year in the large medical meeting so held

If there be any political desire in relation to this position it must emanate, according to this bill, among the doctors themselves, and as a group appearing before this legislature from year to year it is a fair criterion to say that they are non-partisan but are zealous in behalf of maintaining the highest standards in this State for public health and for the good of its citizens

Section 81 seems to have been framed most wisely as to the duties of the medical director, while section 82 would now place squarely upon the group of physicians the responsibility of seeing that cases were actually examined from the standpoint of medical or physical disabilities, and in case of the laxity of any of these examining physicians such as has been complained about so much throughout the medical group in relation to some physicians who now pass upon cases or have passed upon cases, that prompt correction may now be had at the hands of the proposed medical director

This will be, from present judgment, of the utmost benefit in driving out that group of physicians who have not at heart the real purport of their duty, but look upon the question as one of financial gain purely, and in this one move alone the present situation will be infinitely bettered

Section 83 has also been well drawn, but might have contained therein a limiting clause relative to the medical specialist or disinterested medical authority that he be a practitioner licensed in this

## CONDUCT OF PHARMACIES BY CORPORATIONS

In opposition to Senate Bill Introductory No 632, Print No 660, concurrent *Assembly Introductory No 802*, Print No 824, entitled "To amend the public health law, in relation to the conduct of pharmacies by corporations"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of the Medical Societies of the various Counties, begs leave to enter its objection to the above bill for the following reasons

It is to the practicing physician's interest and also to the public's interest, that pharmacies and drug stores, where pharmaceutical prescriptions are filled, should be of the highest standard and integrity. A physician asking a druggist to fill a prescription, is giving into the hands of that druggist that welfare of his patient, and the sick

person to whom the drug is administered—it can readily be seen—is placing his life against the accuracy and intelligence of the druggist. This being the case, we physicians cannot too strongly urge upon your committee that nothing be done that might jeopardize this relationship which has just been outlined, must exist between the physician and his patient.

Drug stores are permitted to dispense alcohol for medicinal purpose, and the great profit there is in this business has, in many instances, admitted persons to open stores and advertise them as drug stores, although no attempt is made to cater to any business except dispensing alcohol.

This bill would license such prostitution and we trust the committee will oppose it. The law, as it stands at present, covers the situation adequately and nothing would be gained by passing the amendment.

## INJURED EMPLOYEES

In support of Senate Bill Introductory No 380, Print No 385, concurrent *Assembly Introductory No 570*, Print No 573, entitled "To amend the workmen's compensation law, in relation to medical attendance and surgical treatment for an injured employee."

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, begs leave to state that it is in favor of the principle involved in this amendment.

We have always contended that the most satisfactory relationship between physician and patient exists only when the patient has implicit confidence in the physician, and this usually is dependent upon whether he selected the physician himself.

We are sure that an amendment of this character would not only make medical attendance more satisfactory for the physician, but would, likewise, result in a great saving to the employer.

## PHYSICAL EXAMINATIONS AND PRACTICAL TESTS OF CLAIMANTS FOR WORKMEN'S COMPENSATION

Brief in opposition to Senate Bill Introductory No 647, Print No 677, concurrent *Assembly Introductory No 184*, Print No 184, entitled "To amend the workmen's compensation law, in relation to not requiring technical rules of evidence or procedure."

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various counties, begs leave to offer its opposition to the enactment of this amendment for this reason.

That it places "physical examinations and practical tests of claimants to determine loss of use and proportionate loss of use of a member" in the hands of persons other than physicians. We

contend that only physicians can interpret the findings of a physical examination or test made upon an injured person. The injury may have been of such nature as to leave a disablement in the patient, with little or no outward evidence of the same. Thus the physician, owing to his knowledge of anatomy and physiology, may be able to discover and estimate, while to a lay person none of those signs and symptoms may be evident, upon which the physician is basing his report. If there is an idea of malingerer, it is quite certain that the physician should make the discovery as quickly as would a layman, with less possibility of making a mistake.

We, therefore, wish to register our opposition to the amendment unless provision is made that the examination shall be made by a physician.

State, thus countering the possibility of medical men entering from another State on invitation and questionably practicing medicine under the present definition when it is to be recognized that the State of New York holds a reputation second to none in its educational and medical requirements

The question of fees has brought forth such a storm that it would seem the wording throughout the bill will react to great good against those unprincipled physicians as occasionally may be seen who would attempt to extort from the State as much as the traffic can be made to bear through pressure from the political or personal side, while at the same time in this same wording, that physician who renders satisfactory care and brings his patient through to speedy recovery now need have no fear that he will be brow-beaten as to his fee for services rendered and in despair offer to settle his bill for a less amount, as reported in some instances

It is also to be hoped from the manner in which this bill is drawn that the fees of the physician will be more promptly paid than have been many cases in the past, while with the giving of greater authority to the medical director, the cases will undoubtedly receive under this new scheme more prompt judgment and quicker decision, thus allowing of appeal sooner if necessary than at present is the case in many instances

In the hope that your Committee will see fit to report this bill out rests a settlement of some and possibly to a large part of the difficulties which confront the medical profession in their discussions whenever they are grouped for conference

Respectfully submitted,

JAMES N VANDER VEER,  
Chairman, Committee on Legislation

### HABIT FORMING DRUGS

In support of Senate Bill Introductory No 115, Print No 115, concurrent *Assembly Introductory No 215*, Print No 215, entitled "To amend the public health law, in relation to habit forming drugs, to provide for the control, possession, sale, prescribing, dispensing, dealing in and distribution of such drugs"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, begs leave to enter its approval of the above bill

Some members of the committee may recall that this bill is the result of amendments to a bill along the same line that was introduced last year. These amendments have made the bill entirely satisfactory to the medical profession and it, therefore, urges its passage

There is most decidedly a need for such legislation and the Society believes this bill meets the conditions as nearly as it could be expected any enactment should. We, therefore, urge that your committee give its approval to the bill and strive for its enactment

### CONCERNING CADAVERS

In support of Senate Bill Introductory No 851, Print No 897, concurrent *Assembly Introductory No 1027*, Print No 1090, entitled "To amend section three hundred and sixteen of the public health law, in relation to cadavers"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, begs leave to enter its approval of the above bill and would request that it be reported out favorably by the committee at its earliest opportunity. A brief statement for its approval follows

It is highly essential that medical schools have sufficient material for adequately training their students in anatomy. The bodies left unclaimed at the institutions mentioned in the bill can serve no better purpose than to be distributed among

the medical schools for student dissection, otherwise their disposition would be an expense to the community and they would serve no purpose, while here they can contribute definitely to the advancement of science. Ample provision is made in the bill to prevent, by accident, the disposition of the body of a person who may have friends who would be interested in giving it a decent burial

Accuracy in diagnosis of diseases in the living is largely dependent upon a study of pathological lesions found by post mortem examination of persons dying of such diseases. Therefore, the physicians connected with hospitals should be granted the privilege of making such scientific investigation upon the bodies of all those persons dying, for whom no provision for burial is made

Respectfully submitted,

JAMES N VANDER VEER,  
Chairman Committee on Legislation

## SANITATION IN FACTORIES AND STORES SELLING FOOD

Brief in support of Assembly Bill Introductory No 678, Print No 688, entitled "To amend the public health law, in relation to sanitation in factories, stores and shops engaged in the business of selling food"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, begs leave to state that it approves of the subject matter of this bill and would like to see a law embodying its principles enacted, but believes that if the above bill should become a law it would be difficult to enforce it, because the physical examination at regular intervals, which it would require of food handlers, will not be understood by the average person and the value appreciated

Employees, not appreciating the importance of such an examination, would not cooperate with the physician by supplying him with the specimens and accurate data necessary for a satisfactory examination and might, on the other hand, think that the procedure was intended to provide employers with data to be used against an employee when desired

A considerable expense would be involved, also, in such periodic examination, which might work a hardship upon the employee or upon the employer, depending upon who was obliged to pay for the services of the examiner

It might be well, in the present bill, to confine the examination to the detection of a few of those diseases whose communicability is well known

## THE CLOSING DAYS OF THE LEGISLATURE

The Legislature has resolved to terminate its business by Friday, March 27th, and, therefore, according to its custom, it will proceed with its business under the Committee on Rules after March 17. The various committees will complete their work and make their final report on March 16. All bills that are not finally disposed of either by being reported out or by having been voted upon unfavorably, will pass to the jurisdiction of the Committee on Rules, and such as remain and go to them may, according to its judgment, be reported out at any time it see fit

Action during these last ten days, therefore, may be very rapid. And, during this period, final action on the bills that have been reported out will be expedited according to the custom of this committee, hence, it is quite essential that the legislators should be informed by their constituents as to the action they desire on any bills that remain unpassed on March 17th. Among these, of course, are our Medical Practice Act and the several chiropractic bills that have been reported out

The Committee on Legislation feels that since there are no longer any members of the State Society who desire to oppose the Karle-Dunmore bill, the probability of its being passed is materially greater this year. Every effort should be made by the physicians, individually and in their Societies, to let their legislators understand that this unity exists and, likewise, that the physicians are firmly combined in opinion against the passage of any of the chiropractic bills, no matter how drastically they may be drawn

Definite, possibly final action can be expected within the next week

No bills were introduced either into the Senate or Assembly during the past week that would affect the practice of medicine. Some of those that were introduced before have been reported out of committee and others have been advanced. Quite a number are still lying with the committee, some of which, without doubt, will never be reported out

## CENSORS OF THE STATE MEDICAL SOCIETY

Brief in support of *Assembly Bill Introductory No 1348*, Print No 1460, concurrent Senate Introductory No 1176, Print No 1283, entitled "To repeal section three of chapter two hundred and six of the laws of eighteen hundred and eighteen, entitled 'An act to amend an act, entitled 'An act to incorporate medical societies for the purpose of regulating the practice of physic and surgery in this state as amended by chapter six hundred and forty-seven of the laws of eighteen hundred and eighty seven'," relating to the appointment of censors by the state medical society"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment

of all of the Medical Societies of the various Counties, begs the committee to report this bill favorably

The object of the bill is to repeal this section of the laws of 1818 which was left in force by the amendment of 1887. What remains is obsolete because it specifies the number of censors that the Medical Society shall elect for its own committee, which is now incorporated in the by-laws of the Society and, therefore, it is unnecessary that it should remain any longer on the statute books

It is simply an attempt on the part of the Medical Society to remove from the laws an obsolete section

## MEDICAL SERVICES IN PUBLIC SCHOOLS

Brief in opposition to *Assembly Bill Introductory No 127*, Print No 1337, entitled "To amend the education law, in relation to medical services in the schools of the state"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, wishes to offer its opposition to the enactment of this bill. It has several very undesirable features

*First* What it is intended to cover is already taken care of by the Department of Education through its division of school inspection

*Second* It attempts to provide for school children a particular group of physicians, surgeons, dentists, pediatricists and nurses, who shall be paid by the State for the services they render and who shall be asked to examine all children with the idea of treating and correcting physical defects discovered. The proper person to care for a school child is the family physician, he alone is familiar with the conditions under which the child was born and grew to the school age. He, therefore, can give the best service and the child remains for the greater portion of the twenty-four hours in his care, insomuch as when he is taken ill at home it is the family physician who will be called. Medical attention should not be divided thus between two physicians, and especially is this true in case of children. The school physician might find some reason for prescribing or treating a child while in school, the result or effect of which may react in a way not

anticipated, after the child has reached home, in which case, of course, the family physician will be called and he will not be able to prescribe intelligently because he will not know to what the child was subjected in school

The most satisfactory way is that in which the work is done at present, where inspectors are employed by the school authorities to examine children at regular intervals and turn the results of their examinations to the parents, with their suggestions as to what action the parents should take

*Third* It is wrong in principle to employ physicians, surgeons, etc., on full time to give attention to school children, because all of the children will not need attention, while some may need a great deal of care, thus the community at large will be taxed to care for the small group who will need their services. If those who need medical or surgical attention cannot afford to pay for it, there are public clinics where they will receive the best of medical care and attention

On the other hand, if they can afford to pay for the attention they need, it is an imposition on the community to ask them to pay the charges of the care their children receive

Therefore, we urge your committee not to pass this bill unless it be drawn so as to coordinate with the laws already in force under which the Department of Education, through its division of school inspection, is operating, or until such amendments are made which will make it accord with the ideas and principles of the laws already in force

## SANITATION IN FACTORIES AND STORES SELLING FOOD

Brief in support of Assembly Bill Introductory No 678, Print No 688, entitled "To amend the public health law, in relation to sanitation in factories, stores and shops engaged in the business of selling food"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, begs leave to state that it approves of the subject matter of this bill and would like to see a law embodying its principles enacted, but believes that if the above bill should become a law it would be difficult to enforce it, because the physical examination at regular intervals, which it would require of food handlers, will not be understood by the average person and the value appreciated

Brief in opposition to *Assembly Bill Introductory No 127*, Print No 1337, entitled "To amend the education law, in relation to medical services in the schools of the state"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, wishes to offer its opposition to the enactment of this bill. It has several very undesirable features

*First* What it is intended to cover is already taken care of by the Department of Education through its division of school inspection

*Second* It attempts to provide for school children a particular group of physicians, surgeons, dentists, pediatricists and nurses, who shall be paid by the State for the services they render and who shall be asked to examine all children with the idea of treating and correcting physical defects discovered. The proper person to care for a school child is the family physician, he alone is familiar with the conditions under which the child was born and grew to the school age. He, therefore, can give the best service and the child remains for the greater portion of the twenty-four hours in his care, insomuch as when he is taken ill at home it is the family physician who will be called. Medical attention should not be divided thus between two physicians, and especially is this true in case of children. The school physician might find some reason for prescribing or treating a child while in school, the result or effect of which may react in a way not

anticipated, after the child has reached home, in which case, of course, the family physician will be called and he will not be able to prescribe intelligently because he will not know to what the child was subjected in school

The most satisfactory way is that in which the work is done at present, where inspectors are employed by the school authorities to examine children at regular intervals and turn the results of their examinations to the parents, with their suggestions as to what action the parents should take

*Third* It is wrong in principle to employ physicians, surgeons, etc., on full time to give attention to school children, because all of the children will not need attention, while some may need a great deal of care, thus the community at large will be taxed to care for the small group who will need their services. If those who need medical or surgical attention cannot afford to pay for it, there are public clinics where they will receive the best of medical care and attention

On the other hand, if they can afford to pay for the attention they need, it is an imposition on the community to ask them to pay the charges of the care their children receive

Therefore, we urge your committee not to pass this bill unless it be drawn so as to coordinate with the laws already in force under which the Department of Education, through its division of school inspection, is operating, or until such amendments are made which will make it accord with the ideas and principles of the laws already in force

## SANITATION IN FACTORIES AND STORES SELLING FOOD

Brief in support of Assembly Bill Introductory No 678, Print No 688, entitled "To amend the public health law, in relation to sanitation in factories, stores and shops engaged in the business of selling food"

The Medical Society of the State of New York, composed of over ten thousand physicians and representing in a majority degree the sentiment of all of the Medical Societies of the various Counties, begs leave to state that it approves of the subject matter of this bill and would like to see a law embodying its principles enacted, but believes that if the above bill should become a law it would be difficult to enforce it, because the physical examination at regular intervals, which it would require of food handlers, will not be understood by the average person and the value appreciated

Employees, not appreciating the importance of such an examination, would not cooperate with the physician by supplying him with the specimens and accurate data necessary for a satisfactory examination and might, on the other hand, think that the procedure was intended to provide employers with data to be used against an employee when desired

A considerable expense would be involved, also, in such periodic examination, which might work a hardship upon the employee or upon the employer, depending upon who was obliged to pay for the services of the examiner

It might be well, in the present bill, to confine the examination to the detection of a few of those diseases whose communicability is well known

## THE CLOSING DAYS OF THE LEGISLATURE

The Legislature has resolved to terminate its business by Friday, March 27th, and, therefore, according to its custom, it will proceed with its business under the Committee on Rules after March 17 The various committees will complete their work and make their final report on March 16 All bills that are not finally disposed of either by being reported out or by having been voted upon unfavorably, will pass to the jurisdiction of the Committee on Rules, and such as remain and go to them may, according to its judgment, be reported out at any time it see fit

Action during these last ten days, therefore, may be very rapid And, during this period, final action on the bills that have been reported out will be expedited according to the custom of this committee, hence, it is quite essential that the legislators should be informed by their constituents as to the action they desire on any bills that remain unpassed on March 17th Among these, of course, are our Medical Practice Act and the several chiropractic bills that have been reported out

The Committee on Legislation feels that since there are no longer any members of the State Society who desire to oppose the Karle-Dunmore bill, the probability of its being passed is materially greater this year Every effort should be made by the physicians, individually and in their Societies, to let their legislators understand that this unity exists and, likewise, that the physicians are firmly combined in opinion against the passage of any of the chiropractic bills, no matter how drastically, they may be drawn

Definite, possibly final action can be expected within the next week

No bills were introduced either into the Senate or Assembly during the past week that would affect the practice of medicine Some of those that were introduced before have been reported out of committee and others have been advanced Quite a number are still lying with the committee, some of which, without doubt, will never be reported out.

## SUMMARY OF BILLS INTRODUCED IN LEGISLATURE IN SENATE

### Prohibition Enforcement

Senate Int No 29 (conc Assembly Int 527)  
—No action has been taken on the Senate bill

The concurrent Assembly bill was reported on February 24, amended, March 2, third reading, March 10, passed, March 11, to Senate Codes Committee

### The Narcotic Bill

Senate Int No 115 (conc Assembly Int 215)

*Comment* At the hearing before the Senate and Assembly Committees on Public Health held on Wednesday, March 11th, this bill received a great deal of consideration. It was supported particularly by Dr Carleton Simon, Deputy Police Commissioner of New York, and Prof J P Chamberlain of Columbia University, representatives of the drug manufacturers led the opposition.

Several amendments were suggested and accepted. After these have been written in, the bill very likely will be reported out of committee into the Assembly.

### Requiring the Licensing of Private Institutions for the Treatment of Drug Addicts

Senate Int No 116 (conc Assembly Int 216)  
—Still in committee. No progress.

### The State Department of Education Bill Amending the Medical Practice Act

Senate Int No 211 (conc Assembly Int 307)

*Comment* There are ten bills which affect the practice of medicine now before the Legislature at the present time—four of them before the Senate and six before the Assembly.

### In Senate

Senate Int 211—The Karle Bill (Medical Practice)

Senate Int 473—The Gibbs Bill (Drugless Therapy)

Senate Int 944—The Fearon Bill (Chiropractic)

Senate Int 789—The Bouton Bill (Chiropractic)

### In Assembly

Assembly Int 185—The Nicoll Bill (Chiropractic)

Assembly Int 307—The Dunmore Bill (Chiropractic)

Assembly Int 649—The Esmond Bill (Chiropractic)

Assembly Int 1343—The Esmond Bill (Chiropractic)

Assembly Int 1423—The Jenks Bill (Chiropractic)

Assembly Int 1463—The Bolton Bill (Chiropractic)

Two of the above mentioned bills are concurrent bills, namely the Karle-Dunmore Bill, and the Fearon-Jenks Bill.

Since the joint hearing on Wednesday March 4th, the Assembly Committee of Public Health has reported out with slight amendments the Dunmore Bill, the Esmond Bill (Assembly Int 649) and the Jenks Bill (Assembly Int 1423).

The bills have not been considered by the Senate Committee on Public Health, but will very likely receive such consideration the early part of the coming week (beginning March 16th) and it is quite probable that two bills, namely the Karle Bill (Senate Int 211) and the Fearon Bill (Senate Int 944) will be reported out.

Your Committee on Legislation urges you to do your utmost now to see that your legislators support the Karle-Dunmore Bill (Senate Int 211, Assembly Int 307).

Our latest information is that there will no longer be any opposition by physicians in the Society to the Karle-Dunmore Bill, at the same time your legislators should be instructed to oppose the passage of either of the other two bills which will be reported out namely, the Fearon Bill (Senate Int. 944) and the Esmond Bill (Assembly Int 649).

The slight amendments made to the bills are as follows:

First, Art 1 of section 172, where it states that "this article shall not be construed so as to prevent the following (1) the practice of medicine, etc, etc., (2) this subdivision has been broadened so as to include physicians or internes employed in any state hospital or institution in which medical service is provided, and subdivision 7 amended so as to include with chiropractic and dentistry "or optometry."

Second, section 170, subsection d, so as to reintroduce among those causes for revocation of certificates and annulment of registration the violation of any of the provisions of Section 1142 of the Penal Law.

Third, that section which has to do with penalties (Section 173, subsection 6) has been modified by dropping from the sentence which describes the custody of committed persons the words "Sundays and legal holidays included," also the final sentence, viz "The provisions of this article relative to imprisonment for such debts shall be exclusive, and the provisions of the debtor and creditor law and of section seventy-

two of the civil rights law shall have no application, and prosecutions for a crime under this article shall not bar prosecutions for civil penalties"

These amendments were suggested by persons at the hearing and accepted by the Department of Education. The same amendments have been seized as well by Senator Fearon for his bill (Senate Int 944) and by Mr Jenks (Assembly Int. 1423), and by Mr Esmond (Assembly 649)

The Assembly Committee on Public Health has reported out the Jenks bill with the amendments as stated above for the Karle-Dunmore Bill and, in addition, an amendment prohibiting the chiropractor from treating any communicable disease

Mr Esmond had his bill (A Int 649) amended to correspond with the Karle-Dunmore Bill, and in addition under the waiver clause of his bill "C" he reduces the period of practice from 10 to 8 years and requires that in addition those who would claim licenses under this clause shall be graduates of a legally chartered school or college of chiropractic within the United States which at the time of his or her graduation required a course of study including the subjects of anatomy, physiology, pathology, hygiene, analytical chemistry and the theory and practice of chiropractic. He introduced a provision also which is intended to make uniform the examinations of those seeking a license to practice medicine or chiropractic, excepting the subjects of materia medica and chiropractic analysis and the science and practice of chiropractic

#### **Inspection by State Charities Boards of Children's Institutions**

Senate Int No 228 (conc Assembly Int 236)  
—This bill is still in committee. No further comment

#### **Qualifications of Examiners in Lunacy**

Senate Int No 263—Bill still in committee  
No further comment

#### **County Public Health Nurses**

Senate Int No 283 (conc Assembly Int 399)

*Comment* This bill has been amended and reported out of committee as so amended both in Senate and Assembly

The amendment follows

It is stated that the public health nurse shall take direction from a committee of the board of supervisors which committee shall be composed of two supervisors and two physicians, members of the County Medical Society, preferably health officers, and one or two lay persons. That part of the bill which attempted to outline the duties

of the nurse has been stricken out, and it specifies that the school nurse shall be under the direction of the school medical inspector

These amendments are in accord with the wishes of the Society as expressed at the Conference of County Legislative Chairmen

#### **Health Service in Schools**

Senate Int No 302 (conc Assembly Int 748)  
—February 9, Amend and recommit, March 11, Rept amended

*Comment* In our first comment on this bill we objected to the use of the term "health experts". The bill has now been amended by striking out "experts" and substituting "and dentists, dental hygienists" or "assistants"

The bill now meets with the approval of the Society and will not be further opposed

#### **Vaccine Virus**

Senate Int No 351 (conc Assembly Int 536)  
—The Assembly bill has been passed and is now in the Senate Public Health Committee

#### **Injured Employee to Select His Physician**

Senate Int. No 380 (conc Assembly Int 570)  
—Still in committee, no further comment

#### **The Drugless Practitioner Bill—(By Gibbs)**

Senate Int No 473

*Comment* This bill is still in Senate Public Health Committee. *See comment on other cult bills under Sen Int 211*

#### **Inspection of School Children**

Senate Int No 586 (conc. Assembly Int. 850)

*Comment* This bill has passed the Senate and is now in the Assembly Public Education Committee

#### **Free Choice of Physician**

Senate Int No 594 (conc Assembly Int 301)  
—Still in committee, no further comment

#### **Practical Tests of Injured Persons**

Senate Int No 647 (conc Assembly Int 184)  
—Still in committee, no further comment

#### **Physically Handicapped Persons**

Senate Int No 671 (conc Assembly Int 868)  
—Still in committee, no further comment

#### **Abolishing Office of Coroner—Westchester County**

Senate Int. No 673—Bill passed both houses  
Now before Governor

#### **Admission of Foreign Practitioners**

Senate Int No 693 (conc. Assembly Int 950)  
—Still in committee. No further comment

**In Relation to Pharmacies**

Senate Int No 632 (conc Assembly Int 802)

*Comment* This bill was brought up at the hearing before the Public Health Committees on March 11th and considerable opposition developed on the part of pharmacists

**Revocation of License to Practice Medicine**

Senate Int No 701—Still in Committee, no further comment

**Hospital for Crippled Children at West Haverstraw**

Senate Int No 786 (conc Assembly Int 1074)—Still in committee, no further comment

**State Institute for Study of Malignant Disease**

Senate Int No 787 (conc Assembly Int 973)—Still in committee, no further comment

**Rural Hygiene**

Senate Int No 716 (conc Assembly Int 969)—Still in committee This bill will be dropped

**The Bouton Chiropractic Bill**

Senate Int No 789

*Comment* See comment on other cult bills under Senate Int 211

**Dissecting Material**

Senate Int No 851 (conc Assembly Int 1027)

*Comment* No particular opposition has developed to this bill, and it is quite possible that it will be passed

**Laboratory Supplies**

Senate Int No 943 (conc Assembly Int 1167)

*Comment* This bill has been withdrawn by the Department of Health

**A Chiropractic Bill**

(By Mr Fearon)

Senate Int No 944 (conc Assembly Int 1423)

*Comment* See comment on this bill under Senate Int 211

**Foreign Licenses**

Senate Int No 1123 (conc Assembly Int 1478)—This bill is on order of third reading in the Senate.

**Censors of State Medical Society**

Senate Int No 1176 (conc Assembly Int 1348)

*Comment* This bill is progressing was rept on March 12th, third reading on the 13th

No opposition has developed and it will without doubt have an uneventful career and be passed as we desire

**IN ASSEMBLY****Health Service in Schools**

Assembly Int No 127—Still in committee, no further comment

**Practical Tests of Injured Persons**

Assembly Int No 184 (conc Senate Int 647)—See concurrent Senate Int 647

**The Nicoll Chiropractic Bill**

Ways and Means Committee

No 1595

Int No 1463

IN ASSEMBLY

March 4, 1925

Introduced by Mr Bolton—(by request)—read once and  
referred to the Committee on Ways and Means

**AN ACT\***

To amend the public health law, creating a board of  
chiropractic examiners and regulating the practice of  
chiropractic and prohibiting the practice of any other  
mode or system under the name of chiropractic.

*The People of the State of New York represented in  
Senate and Assembly, do enact as follows*

Section 1 Chapter forty-nine of the laws of  
nineteen hundred and nine, entitled "An act in  
relation to the public health, constituting chapter  
forty-five of the consolidated laws," is hereby  
amended by inserting therein a new article, to  
follow article eight-a, to be article eight-b, to read  
as follows

\* Matter in italics is new, matter in brackets [ ] is old law  
to be omitted.

## ARTICLE 8-B

§ 189 Creation of a board There is hereby created, a board of chiropractic examiners, to be known as the state board of chiropractic examiners

The board of chiropractic examiners shall consist of three members who shall be appointed by the governor within thirty days after this article takes effect

The appointees shall meet within ten days after their appointment and organize by electing a president, secretary and treasurer, and adopting reasonable rules and regulations for the transaction of business

The appointees shall have the qualifications set forth in section one hundred and eighty-nine-h of this article Subsequent appointees shall be graduates of chiropractic schools or colleges giving a course of at least three years of six months each, in anatomy, physiology, symptomatology, hygiene, sanitation, chiropractic analysis and the principles and practice of chiropractic and requiring actual attendance upon the classes No one may be appointed who practices anything but chiropractic as hereinafter defined

The term of office of the first member shall be one year, the second, two years, the third, three years Appointees after the first shall serve for three years, and until their successors shall have been duly appointed and qualified Vacancies shall be filled by the governor within thirty days

§ 189-a Meetings The board shall hold regular meetings to examine applicants and the transaction of business, commencing on the first Mondays of March, August and November, in each year Special meetings may be called by the president and secretary upon thirty days notice printed in a newspaper of general circulation in the state

§ 189-b Offices The superintendent of public buildings shall, at the request of the board, provide an office where meetings may be held Special meetings may be called anywhere in the state

§ 189-c Eligibility Any person of good moral character, who is a graduate of a chiropractic school or college teaching chiropractic, and giving a course of at least three years of six months each in the subjects numerated in section one hundred and eighty-nine, and requiring actual attendance upon the classes, shall be eligible to examination, provided he possesses preliminary education or experience equivalent to a high school education, and provided further, that he practices nothing but chiropractic, as hereinafter defined

§ 189-d Chiropractic defined Chiropractic is defined to be the science of palpating and adjusting the articulations of the human spinal column by hand only This definition is inclusive and

any and all other methods are hereby declared not to be chiropractic

§ 189-e Practitioners No person shall practice chiropractic without a license, which license shall not entitle him to practice anything else. And, no one may hold himself out as a chiropractor without having a license

§ 189-f Examinations Anyone desiring an examination, shall, at least fifteen days prior to the meeting of the board, make written application to the secretary Such application shall be accompanied by an examination fee of fifteen dollars The application shall state the name, age, sex, and place of residence of the applicant, the name and location of the school or college from which he graduated, the length of time devoted to the study of chiropractic, the date of graduation, together with such other data as the applicant may desire to give In case an applicant fails in the first examination, he shall be entitled to a second one, without further fee Application shall be signed and sworn to by the applicant

The board shall prepare reasonable questions, and fairly mark and grade the answers thereto, all of which shall be done solely for the purpose of determining whether the applicant is reasonably qualified to practice chiropractic All applicants reasonably qualified to practice chiropractic shall be granted a license

§ 189-g Licenses All licenses shall be signed by the president and secretary of the board, and shall be attested by the official seal of the board The licensee shall pay to the secretary of the board before the license is issued a fee of five dollars Every license to practice chiropractic shall, before the licensee begins practice thereunder, be registered in a book kept in the clerk's office of the county where such practice is to be carried on, with name, residence, place and date of birth, and source, number and date of license to practice

Every licensee shall be required to pay to the secretary of board an annual renewal license fee of two dollars

§ 189-h Licenses without examination Any person of good moral character who has been continuously engaged in the practice of chiropractic in the state for two years prior to the passage of this article shall be licensed without examination, upon payment to the secretary of the board of a fee of twenty dollars, if he applies for a license within twenty days after the organization of the board

§ 189-i Reciprocity Any person of good moral character, licensed by a chiropractic board of any other state or territory or holding a certificate from the national board of chiropractic examiners, shall be licensed without examination, upon payment to the secretary of the board of a fee of twenty dollars

§ 189-j Revocation Upon complaint to the

board, after twenty days' notice of time and place of trial has been given to any licensee, if it shall be found that he practices anything other than chiropractic to cure or relieve disease or to remove the cause thereof without having a separate license therefor, or, if it be found that he no longer possesses a good moral character or is addicted to the use of narcotic drugs or in any way is guilty of deception or fraud in the practice of chiropractic, his license shall be revoked

The action of the board shall be reviewable by certiorari proceedings

§ 189-k Finances Within ten days after the close of every meeting of the board, the treasurer of the board shall turn over to the state treasurer, all fees and money received by the board, and take his receipt therefor

The state treasurer shall keep the same in a separate fund, to be used in paying running expenses of the board and a per diem compensation of fifteen dollars to the members thereof for such time as they may actually spend in the discharge of their official duties and traveling expenses

Payments from such fund shall be made by the state treasurer on the warrant of the comptroller and the vouchers of the president of the board

If, at the close of any fiscal year, there remains in the hands of the state treasurer from moneys received from the board, one thousand dollars in excess of all indebtedness of the board, the same shall be turned over to the public school fund

§ 189-l Penalties Any person violating any of the provisions of this article shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished by a fine not to exceed three hundred dollars or by imprisonment for a term not to exceed three months, or by both such fine and imprisonment.

§ 2 Repeal All acts or parts of acts in conflict with this article, are hereby repealed

§ 3 When act to take effect This act shall take effect immediately

## IODIZED SALT TRADE FLOURISHES IN LOCKPORT

The Division of Communicable Diseases has received a number of interesting communications from Dr Thomas E Spaulding, health officer of Lockport, on the subject of the use of iodized salt in his community. Early in February, Dr Spaulding distributed in the public, private and parochial schools of the city, about 4,200 circulars on goiter prevention through the use of iodized salt instead of ordinary table salt. This was apparently followed by a rushing business in the salt trade. Dr Spaulding states that no less than seven wholesale houses are supplying the local grocers with iodized salt. The usual retail price is 15 cents for a two-pound package.

Dr Spaulding reports that representatives of one firm stated that they had wholesaled 35 cases of 24 packages each to local grocers, and that they had orders for 15 cases, but that the orders were not filled, as available stock was exhausted, although a carload was on the way to the city. He believes that other firms are doing a similar business.

This method of preventing simple goiter is one that is available to any health officer with very little trouble or expense. Further reports on developments in Lockport will be awaited with interest.

The chief difficulty in prevailing on the general public to use the method seems to be the excess-

ive price which is charged for the iodized salt—which contains only .02 per cent of potassium or sodium iodide. The actual retail price for this amount of iodide is less than two-tenths of a cent for each pound of salt. As table salt in convenient packages commonly sells at the rate of five cents a pound, it is difficult to understand why the addition of the iodide should cause an increase of 50 per cent in the price. Possibly increased competition in meeting a larger demand for the iodized salt will result in reducing the excess charge. Even at present prices, however, the use of iodized salt in the home instead of common salt is an insignificant expense, and is far cheaper than other methods of goiter prevention—such as the use of iodide tablets, or the introduction of iodine into the public water supply. It is stated that practically all large salt producers are marketing an iodized salt, and retailers should experience little difficulty in obtaining it through wholesalers and jobbers.

In view of the widespread prevalence of simple goiter in many states, it seems possible that the most practicable way to eliminate the disease would be to compel, by federal enactment, the iodization of all table salt carried in interstate trade. If this were done, the considerable effort now being made by health and educational authorities in combating goiter would be unnecessary.

## NEWBURGH RECOVERS BOY WHO BROKE QUARANTINE

A clipping from the *Middletown Times* of January 20 states that following the escape of a Newburgh boy from his home which was under quarantine for scarlet fever, Dr Thomas J Burke, health officer of Newburgh, discovered that this boy had taken a bus for Middletown.

The facts were reported by him to Dr H J Shelley, local health officer, who found that the child was in a restaurant owned by the boy's uncle. The return of the boy to Newburgh in a private automobile was then ordered.

## "TRENCH" ITCH PROVES TO BE URTICARIA

A story in a Nyack paper a week or so ago gave an account of an outbreak of skin disease at Fishkill Village which affected both children and adults and which was said to have been diagnosed as "Trench Itch" but which was thought by many to be the "Seven Year Itch."

Investigation by one of the district state health officers disclosed the fact that most of these cases were in reality urticaria and that in all cases the families had been breakfasting largely on buck-wheat cakes or had eaten pork recently.

## CONTROLLING SYPHILITIC INCORRIGIBLES

The United States Public Health Service has thought it of enough importance recently to send out a news release calling attention to the fact that the Salt Lake City board of health in co-operation with the state board of health of Utah has been making a systematic effort to quarantine all men and women found under circumstances which give rise to a reasonable suspicion that they have a venereal disease. Under this rule, any situation which will warrant a reasonable inference that the persons are engaged in prostitution or promiscuity provides legal sanction for compelling an examination, and, if an infection is shown, to establish a quarantine and enforce treatment. Both men and women are subject to the working of the measure.

It may not be generally known that New York State has had a very similar "reasonable suspicion" law\* since April 17, 1918. In addition this Department has recommended the following regulation for adoption by municipalities in order that incorrigibles may be better controlled.

"When in the opinion of the health officer it is necessary to safeguard the public, a person affected with syphilis, gonorrhea or chancroid shall be isolated in a hospital, institution or other place designated by the health officer for such period as may be deemed necessary by him."

\* Section 343 of the Public Health Law as added by Chapter 264, Laws of 1918 and amended by Chapter 40, Laws of 1919.

## VACCINATION LATER THAN THREE DAYS AFTER EXPOSURE FAILS TO PROTECT AGAINST SMALLPOX

Through an oversight, a contact to a case of smallpox was recently allowed to go free, although he was not vaccinated until six days after his first exposure. He went to another town and subsequently developed the disease, exposing ten persons.

This is one of many illustrations of the fact that vaccination later than the third day after exposure cannot be depended upon to protect against smallpox, although it may modify the

severity of the attack. Regulation 30, of Chapter II, of the Sanitary Code, provides against this contingency by requiring that persons exposed to smallpox must be quarantined, unless vaccinated within the three-day period. This regulation also stipulates that, when vaccinated, contacts must be kept under observation until the vaccination proves to be successful, or for at least twenty days.

## COMMON UTENSIL SPREADS GONORRHEAL OPHTHALMIA

The innocent contraction of a gonococcus infection is not very frequent, but when cases are reported they are usually infections of the conjunctiva and are of a serious nature. *Venereal Disease Information* for January 1925, reports that two officers in the engineering department of one of our battleships recently developed severe gonococcus infection of the eyes. There was no evidence that either had ever had a venereal disease. A yeoman in the engineer's office was

under treatment for active gonorrhea at the time. The only article used in common was a wash bucket.

The damage to the eyes of the two officers resulted in their being obliged to leave the service, a direct loss to the government not only in personnel, but in money, since many thousands of dollars are expended on the education and training of commissioned officers.

# NEWS NOTES

## REFERENDUM VOTE OF THE HOUSE OF DELEGATES

Referendum vote of the House of Delegates on the Karle-Dunmore Bills canvassed by the tellers appointed by the Council of the Medical Society of the State of New York Polls Closed March 5, 1925

In favor	106	Against	31
E Eliot Harris, Chairman,	Joshua M Van Cott,	George W Whiteside	Tellers

## THE MEDICAL SOCIETY OF THE COUNTY OF QUEENS

A regular meeting of the Medical Society of the County of Queens was held Tuesday, February 24, 1925, 8 30 P M, at the Eagle Place, Jamaica The President, Dr Courten, in the chair

The following physicians were elected to membership Drs Isador Berman, William C Brons, Fred W Backus, Orman Gregersen, Thomas H Grodin, Jordan Lally, Raymond L Sippel, James E Stack

Dr McMahon, Chairman of the Legislative Committee, made the following recommendations as to pending legislation at Albany

1 Opposition to Assembly bill No 422, permitting Physicians and Nurses to disclose Professional Information in certain cases

2 Opposition to State Department of Education Bill, amending the Medical Practice Act, Senate Int No 211 (Conc Int 307)

3 Endorsement of Workmen's Compensation Bill, Senate No 594

These recommendations were approved by vote of the house, the second one being passed by vote of 56 to 4, after prolonged discussion, in which Drs McMahon, Flemming and Barry spoke against the bill, and Drs Steffen, Boettiger and Thomas for it

A resolution instructing the delegates of the society to vote against the bill in the referendum ordered by the Council of the State Society was passed

Dr Flemming reported work done by the committee on membership and on motion the secretary was instructed to send a communication to all hospitals in the borough, requesting that membership on their medical staff be limited to members of the county society

On motion of Dr Chalmers it was voted that the society join with the other societies in the vicinity in an invitation to the American Medical Association to meet in New York City in 1926

Dr J Frank Fraser gave an interesting talk illustrated by lantern slides on the diagnosis and treatment of some common skin diseases

The second paper on "Hemorrhagic Purpura, Treated by Splenectomy and Transfusion" by Robert Emory Brennan, M D, and Carl Boettiger, M D, respectively, Visiting Surgeon and Visiting Physician of St John's Hospital, Long Island City, was read by Dr Boettiger The diagnosis of the condition forming the subject of the paper rests upon the blood picture The similar conditions showing low blood platelet count are bacterial infections, diseases of blood forming organs, as leukaemia, various chemical poisons, and certain nutritive disturbances

Other similar conditions which may be distinguished from hemorrhagic purpura by normal blood platelet count are hemophilia, cholemia, arthritis, Henoch's disease, purpura with arterio sclerosis and congenital vulnerability of capillaries

It is an uncommon disease, characterized by bleeding from mucous membranes and into the skin

The authors reported two cases of the acute type treated by splenectomy, with recovery in one case, the fatal case really being in extremis when operated upon

Conclusion of authors is that splenectomy is life saving in patients suffering from hemorrhagic purpura, when the disease threatens life either by its fulminating character or by chronic bleeding

Transfusion is of no value unless accompanied by splenectomy

JOSEPH S THOMAS, *Secretary*

## OTSEGO COUNTY MEDICAL SOCIETY

The regular meeting of the Otsego County Medical Society was called to order at 4 30 P M, in the Hotel Fenimore, Cooperstown, on March 10, 1925

Dr M H Atkinson was elected to membership

Mr H F Wanvig of New York gave a talk on the Indemnity Insurance approved by the State Society, in which he explained the plan in

full and the advantages which accrue to the members who avail themselves of this insurance.

Dr J C Smith gave an address on the present status of the Medical Practice Act

Dr C W Lanning gave a short history of the early days of the Otsego County Medical Society, founded in 1806

A H BROWNELL, *Secretary*

---

## MEDICAL SOCIETY OF THE COUNTY OF SCHENECTADY

The regular monthly meeting of the Medical Society of the County of Schenectady was held at the Assembly Hall of the Ellis Hospital Tuesday evening, March 10, 1925

The program which consisted of a symposium on expert testimony, was opened by Dr Edward Ellery, Dean of Union University of Schenectady, who commented on expert testimony largely from the chemists' viewpoint. He showed how experts, both of equal ability would often give opposite opinions from examinations of identical specimens with the same methods of chemical analysis. Undoubtedly the testimony of experts is biased in behalf of the litigant by whom they are employed. It would seem, Dr Ellery claimed, that this bias might be overcome by all expert

testimony being employed by the court, and not separate experts by both plaintiff and defendant

The second speaker was Mr Walter Wellman, a prominent attorney of Schenectady. Dr Wellman discussed expert testimony from the courts' viewpoint. Following Mr Wellman, Capt W H Funston, Chief of the Police Bureau, talked on the criminal aspect. He also related some interesting experiences in crime detection occurring during his association with the New York Police Department

The final speaker of the evening was Dr Ellis Kellert, Pathologist of the Ellis Hospital, who took up expert testimony from the pathologist viewpoint

---

## CLINICAL LECTURES OPEN TO GENERAL MEDICAL PROFESSION

The Columbia University Medical School in New York City has just announced that the Clinical Lectures of the third and fourth years will be open hereafter to the general medical profession

These lectures are given at the Medical School, 437 West 59th Street, by Professor John A Fordyce in Dermatology and Syphilology, on

Wednesdays at 3 00, Professor Herbert B Wilcox on Diseases of Children, on Wednesdays at 4 00, Professors Frederick Tilney, Louis Casamajor and others on Neurology on Thursdays at 4 00, Professor Arnold Knapp in Ophthalmology on Wednesdays at 2 00, Professor Thomas W Salmon and others in Psychiatry on Fridays at 5 00

---

## EXAMINATION FOR ENTRANCE INTO THE REGULAR CORPS OF THE U. S PUBLIC HEALTH SERVICE

Examinations of candidates for Regular Corps of the U S Public Health Service will be held at Washington, D C June 1 1925 at Chicago, Ill, June 1, 1925, at New Orleans, La June 1, 1925, at San Francisco, Cal, June 1, 1925

Candidates must be not less than twenty-three nor more than thirty-two years of age, must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice

They must pass satisfactorily, oral, written and clinical tests before a board of medical officers and undergo a physical examination

Successful candidates will be recommended for appointment by the President with the advice and consent of the Senate

Requests for further information should be addressed to H S Cumming, Surgeon General, U S Public Health Service, Washington, D C

## THE GORGAS MEMORIAL

That the Gorgas Memorial Institute is accomplishing its initial purpose of uniting laymen and doctors, and instilling into the masses a recognition of the fact that scientific medicine is the only proper authority in health matters, is evident from newspaper reports the country over.

The Gorgas Memorial Institute appears indeed to be enjoying a healthy growth from the Atlantic to the Pacific. The value of periodic health examinations is being stressed in hundreds of newspaper articles, in public talks and in radio addresses.

Scores of editorials have been written and published by leading newspapers. Without exception they have deep sympathy with the ideals of the organization and heartily endorse it.

A special article written for the *Detroit Saturday Night* and appearing in the issue of February 14 is pertinent. It reads in part:

"Quacks and quackery in the field of medicine and general health protection will receive a heavy blow when the Gorgas Memorial Institute, recently founded in honor of the great army medical man who showed the world that yellow fever and other pestilences could be conquered by preventive methods, gets functioning.

"The Institute is not heralding as one of its purposes the counteracting of propaganda such as is spread by circus strong men and health quacks who use every opportunity to attack the medical profession, but just so far as its plans, as announced, are successful, it will help to overcome pernicious teachings and ignorance regarding health."

The article goes on to say—

"The Institute will carry out General Gorgas' ideas of the exercise of preventive measures and the use of scientific medicine to check disease and wipe out pestilence. It is estimated that modern ideas of sanitation, coupled with the principle of periodic examinations, such as General Gorgas

practiced in the United States army during the World War, would mean a saving of \$1,500,000,000 annually. And the decrease in sickness and increase in happiness would be worth as much more.

"On any given day there are 3,000,000 people on the nation's sick list. One million of these are gainfully employed. The daily loss from this one source is staggering."

The County Societies are also proving receptive to the Gorgas idea. They see in the movement a plan which will aid each member individually.

"What benefit will the Gorgas Memorial be to me, personally?" asks the scientific medical man invited to serve on the New York Governing Committee.

This is the answer:

You will be associated in a definite way with the biggest health movement ever inaugurated—a movement endorsed and supported not only by the medical profession but by civic organizations and the general public.

The publicity attendant on this program will bring before the public, in a way never before attempted, the medical man's importance in community development. The organized strength of the most highly regarded profession in the world today, to protect and carry on the ideals which have actuated it for centuries, cannot fail to react beneficially on the individual as well as the group.

The Directors of the Gorgas Memorial Institute of Tropical and Preventive Medicine are basing their success on the efforts of the thousands of friends of General Gorgas who will volunteer to give their time, influence and money to show their appreciation of his contribution to the happiness of many people and of the efforts he made that resulted in saving thousands of lives and millions of dollars. His life's work, if they succeed, will be projected far into the future in the way that he would have desired.

## DOCTORS' FEES IN THE OLDEN TIME

The physicians of New York City did not work for nothing a century and a quarter ago. On the contrary, the gold-headed cane which was the symbol of the honorable station of the physician in society, should have been well within the means of every doctor if he charged and collected the fees according to the following table which was adopted by the Medical Society of New York City in 1798.

### FEE LIST OF 1798

COPY FROM MINUTES OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

We, the subscribers, practitioners of physic and surgery in the City of New York, do agree upon the following rate of charges, for our professional services, from and after the first day of July, 1798, agreeably to which rates we do recommend our bills to be presented every six months, or oftener if circumstances permit.

Verbal advice	\$5 00
A letter of advice	10 00
An ordinary visit	1 00
A visit, with a single dose of medicine	1 25
Medicine to be priced as follows	
For powders, each	12
Pills, each dose	12
Boluses, each	25
Electuaries, per ounce	50
Mixtures, per ounce	12
Decoctions, one dollar and 50/100 per lb or per ounce	12
Infusions one dollar and 50/100 per lb or per ounce	12
Lotions, per lb	1 25
Tinctures, per ounce	25
Vol. spirit, per ounce	50
Ointments and cerates, per ounce	25
Blistering plaster, according to their sizes, from \$1.25 to	2 00
Other plasters, 50c. to	2 50
For a single dose of medicine, dispensed without a visit	62

### CONSULTATIONS

The first visit in consultation	\$5 00
Each subsequent visit in consultation	2 00
A night visit	5 00
Visit at a distance from town, per mile	1 00
A visit to Brooklyn	3 00
A visit to Pawles' Hook	5 00
A visit to Staten Island	10 00
The last two charges to be doubled in winter or in stormy and tempestuous weather	
The first visit in epidemic fevers, or in other diseases where there is personal danger incurred	
Each subsequent visit under these circumstances	2 00

### THE CHARGES

For curing a simple or virulent gonorrhea, from ten to	\$20 00
For curing confirmed syphilis, from \$25 to	100 00
For dressing a blister, from 50 to	1 00
For dressing wounds, from \$1 00 to	2 00
For applying cupping glasses	4 00
For bleeding in the arm	1 00
For bleeding in the foot	2 00
For bleeding in jugular vein	2 00
For opening an artery	5 00
For inoculating and attending in the small pox, from \$5 00 to	10 00
Scarifications of the eye	5 00
Punctures in oedematous swellings	2 00
Inserting an issue	2 00
Inserting a seton	5 00
Introducing a catheter the first time	5 00
Introducing a catheter each subsequent time	2 00
Extracting a calculus from the urethra	10 00
Reducing a simple fracture, from \$10 00 to	20 00
Reducing a compound fracture	30 00
Setting dislocations, from \$5 00 to	20 00
For reducing a prolapsus ani	5 00
For reducing a hernia	25 00
For opening an abscess, from \$1 00 to	5 00
For amputating the breast	50 00
For amputating an arm or leg	50 00
For amputating a joint	100 00
For amputating a finger	10 00
For amputating the penis	20 00
For extirpating the eye	100 00
For extirpating the tonsil	25 00
For extirpating the testicle	50 00
For extirpating a polypus	25 00
For extirpating a tumor, from \$10 to	50 00
Perforating the rectum, nostrils, or the urethra	10 00
Paracentesis of the abdomen	10 00
Paracentesis of the thorax	50 00
Operation for an aneurism	100 00
Operation for hair lip	25 00
Operation for hydrocele	25 00
Operation for hernia	125 00
Operation for fistula in ano	50 00
Operation for fistula in perineo	25 00
Operation for phymosis	10 00
Operation for paraphymosis	10 00
Operation for fistula lachrymalis	25 00
Operation for wry neck	25 00
Operation for cataract	125 00
The operation of lithotomy	125 00
The operation of bronchotomy	25 00
The operation of trepanning	100 00
The operation of circumcision	10 00

### MIDWIFERY CHARGES

For a common case, from \$15 00 to	25 00
For tedious or difficult cases, from \$25 to	40 00

RESOLVED, that the Secretary transcribe in the Book of Minutes the medical charges agreed upon in the year one thousand seven hundred and ninety-eight. (1798)

Adjourned.

# THE DAILY PRESS

The question of Medical News is discussed by the *Middletown Herald*, February 25th, in an editorial entitled "Physicians and Censorship." This is a sensible exposition of the viewpoint of the newspaper editor toward news of a medical nature. The editor is opposed to medical censorship, as is shown by the following quotation:

"The statement is being made that organized physicians are supporting a movement to place health and medical news under censorship, arguing that newspapers should have medical editors, because the layman journalist cannot write intelligently upon medical subjects. If this report is true, the position of such physicians as may be supporting the movement is to be deprecated, for this censorship would be nothing short of an abridgement of the freedom of the press."

What physicians want is not *censorship*, but *editorship*. We believe that every newspaper should have a medical editor just as it has a sports editor, and a political editor.

The editor has evidently been rebuffed by physicians, for he says:

"Physicians complain from time to time of ridiculous mistakes made in newspapers in the use of medical terms in news stories on health subjects and so on. If it were possible for a physician to censor all medical news, errors would still creep in, just as errors creep into all printed matter, even medical journals. Any plan to censor newspapers as to what they shall and shall not use, be it in the field of medicine or in other fields, will meet with instant and vigorous opposition from the newspaper profession. If physicians who are called by news gatherers, and hospitals, whence medical news emanates, were more explicit in their answers to questions, much of the inaccuracy could be eliminated. If a physician is called by a reporter, and that doctor gives a gruff and hasty response to a civil question, it is hardly to be expected that a news writer can construct a story as intelligently, from the medical viewpoint, as he could if the doctor were obliging enough to furnish him with accurate information."

But the editor hastens to assure the doctors that he has no personal feeling in the matter.

"Insofar as health news in general is concerned, Middletown, at least, can hardly fall within the scope of criticism for inaccuracies, for both the city health officer and the District State Health Officer are most accommodating in furnishing health items, taking pains to aid the reporter in straight and seeing that the medi-

"Newspapers today are printing intelligently news stories of epidemics which half or even a quarter of a century ago would have been so sensationalized as to have worked to the detriment of the very public the physicians wished to calm. With newspapers ready and willing to assist in spreading the gospel of good health, it appears to be up to the physicians to aid to the utmost, instead of criticizing and ridiculing errors which, many times, are made through lack of information from the medical men themselves."

We have noticed that the *Middletown* newspapers have practised what they preach, and we have frequently quoted them in our *Daily Press* department.

Several up-State newspapers comment on the question whether or not a specific cure for tuberculosis would put tuberculosis workers and associations out of a job. The occasion for the articles was an address made by Dr. Linsly R. Williams, Managing Director of the National Tuberculosis Association, before the State Conference on Tuberculosis held in New York during the third week of February. The *Poughkeepsie Eagle*, February 24th, says:

"A specific cure for tuberculosis will not put tuberculosis workers and associations out of a job. Dr. Linsly R. Williams, managing director of the National Tuberculosis Association, discussed the question at the conference and pointed out that the field of work of associations and workers has already broadened to include many other lines of disease prevention. Dr. Williams warned, however, against broadening the scope of work until the tuberculosis problem was solved."

If a cure for tuberculosis should be found, the next great problem will be to get people to take it. A practically sure cure for diphtheria is known and available, but not only do many persons object to taking it, but there is a growing group of cultists who are trying to combat the use of antitoxin, and the result is that diphtheria deaths are still common.

Tuberculosis is still one of the principal causes of death, and all available sanatoriums and hospitals are filled to their capacity. Nurses and physicians are making strenuous efforts to discover new cases, and yet from one-quarter to one-third of all persons dying of tuberculosis are unknown to the doctors and nurses previous to the last few days of their illness. Another third of deaths are among those who refuse to cooperate with the nurses or to obey their doctors. These cases will always be with us, and there is no prospect that tuberculosis will cease to be

a big factor in public health during this quarter century

The *Glens Falls Times* of February 24th also discusses the question of what will become of tuberculosis workers if a cure is found for the disease. The account says

"Tuberculosis associations and workers, it was reported, will not lose their jobs when a specific tuberculosis cure is found, because their field of work has already broadened to include many other lines of disease prevention, and the time was foreseen when associations financed through the Christmas seal sale will engage in campaigns for the prevention of cancer, heart disease and venereal disease. The warning was given, however, not to broaden the scope of the work until the tuberculosis problem was solved"

In our Daily Press department of January 16th we commented on the publicity given to the campaign for the sale of Christmas seals, and mentioned the lack of any reference to any other purpose than that of the suppression of tuberculosis. We note a growing tendency to suggest other uses for the money besides the suppression of tuberculosis. We also note the indication of a growing fear that many workers might lose their positions if the campaign for the suppression of tuberculosis should succeed to the degree that was predicted by the tuberculosis associations some ten years ago.

The physicians of New York State believe in sticking to one program until it has succeeded in its object. The problem of tuberculosis is now understood to a greater extent than ever before, and physicians are becoming more and more interested in the control of the disease. It would be a calamity to divide the forces which are arrayed against tuberculosis.

It is our opinion that as physicians assume more and more control over tuberculosis, there will be more and more demand for the services of nurses and lay workers in the tuberculosis field.

Publicity of epidemics of communicable diseases is often condemned, but when instances of condemnation are investigated, they usually indicate a failure of the governmental officials to institute control measures early in the outbreak. When publicity is given late, there is a feeling that only half the truth is being told, and that conditions are worse than the officials admit. On the other hand, when full publicity is given early in an outbreak, the people are reassured, and feel that conditions are not half so bad as reported.

We are glad to see several favorable comments on publicity in a smallpox case. The *Olean Herald*, March 2nd, has an editorial entitled "Business Men Converted," in which it quotes from the Health News of the State Department

of Health, an account of a protest of business men against publicity in regard to smallpox, but which was changed to approval when a committee of business men investigated conditions. The Olean editorial concludes

"The aversion of business men to publicity in connection with epidemics of contagious or infectious diseases is natural. They fear that such publicity will restrict business, and being only human, they do not like to contemplate such a contingency. This feeling has been manifested from time to time in most communities. Sometimes the newspapers come in for rather severe criticism for telling the public the facts. Where those who object to publicity err is in overlooking the fact, so clearly established in the instance above cited, that only as the facts are made known can proper remedies be applied. To give the facts is the duty of the public press."

The *New York Sun*, March 11th, contains comments on a study of the subject of colds made by the U S Public Health Service, and quoted from the current *Popular Science Monthly*.

"We no longer can be sure of our ground when we blame the weather for a cold in the head or other nose and throat disorders.

"This lack of relationship between colds and the weather in the United States is demonstrated in the startling similarity between cold occurrence in the rigorous North and that in the warmer South and Pacific Coast. In general, New Orleans and San Francisco suffer with Chicago and Boston—and at very nearly the same time of the year.

"The findings of the investigators may be summarized as follows:

"The common cold is extremely contagious. It does not come from bad weather or wet feet, but from germs that attack those whose physical condition makes them susceptible.

"Each of us, on an average, suffers from 37 colds a year.

"October is the worst time of the year for colds. Another bad month is January. June is the month in which you are least likely to catch cold."

Most articles, both medical and lay, on the subject of colds lay great stress on the body as the *soil* in which the infectious germs grow, and say little about the *seed*, or the germs of infection. The article illustrates the importance of the prevention of the spread of disease germs, or, in other words, the isolation of the person who has an acute cold of whatever nature it may be.

We believe that the time is ripe for Departments of Health to start a campaign to educate the people regarding the necessity of isolation of all cases for the prevention of all the forms of sickness which are called colds.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these columns will be made for review, as dictated by their merits, or in the interest of our readers.

- MEDICAL CLINICS OF NORTH AMERICA** Volume 8, Number 2, September, 1924 (Chicago Number) Published every other month by the W B Saunders Company, Phila. and London. Per Clinic Year (6 issues) Cloth, \$16 00 net, paper, \$12 00 net.
- IMMUNITY IN NATURAL INFECTIOUS DISEASE.** By F d'HERELLE. Authorized English Edition by GEORGE H SMITH, Ph D Octavo of 399 pages Baltimore, Williams & Wilkins Company, 1924 Cloth, \$5 00
- HYGIENIC FUNDAMENTALS OF FOOD HANDLING.** By CHARLES THOM and ALBERT C HUNTER of the Microbiological Laboratory, Bureau of Chemistry, U S Department of Agriculture. Octavo of 228 pages, illustrated. Baltimore, Williams & Wilkins Company, 1924 Cloth, \$3 00
- DISEASES OF THE HEART** By Dr HENRI VAQUEZ Translated and edited by GEORGE F LAIDLAW, M D Octavo of 743 pages, illustrated Philadelphia and London, W B Saunders Company, 1924 Cloth, \$8 50
- MANUAL OF PSYCHIATRY FOR THE MEDICAL STUDENT AND GENERAL PRACTITIONER.** By PAUL E BOWERS, M S, M D Octavo of 365 pages Philadelphia and London, W B Saunders Company, 1924 Cloth, \$3 50
- PRACTICE OF PEDIATRICS** By CHARLES GILMORE KERLEY M D, and GAYLORD WILLIS GRAVES, M D Third Edition, revised and reset. Octavo of 922 pages with 150 illustrations Philadelphia and London, W B Saunders Company, 1924 Cloth, \$9 00
- ABT'S PEDIATRICS** By 150 Specialists Edited by ISAAC A ABT, M D Volume 5, containing 865 pages with 373 illustrations (Set to be complete in eight octavo volumes) Philadelphia and London, W B Saunders Company, 1924 Cloth, \$10 per volume Sold by subscriptions
- A TEXT-BOOK OF PATHOLOGY** By W G MACCALLUM, M D Third Edition, thoroughly revised Octavo of 1162 pages with 575 original illustrations. Philadelphia and London, W B Saunders Company, 1924 Cloth, \$10 net
- A MANUAL OF OBSTETRICS** By JOHN COOKE HIRST, M D, F.A.C.S. Second Edition, entirely reset. 12mo of 551 pages with 229 illustrations Philadelphia and London, W B Saunders Company, 1924 Cloth, \$4 50 net.
- MEDICAL CLINICS OF NORTH AMERICA** Volume 8, Number 3, November, 1924 (Philadelphia Number) Published every other month by the W B Saunders Company, Phila. and London. Per Clinic Year (6 issues) Cloth, \$16 00 net, paper, \$12 00 net.
- OPERATIVE SURGERY** Covering the Operative Technic involved in the Operations of General and Special Surgery By WARREN STONE BICKHAM, M D, F.A.C.S. Vol 6, completing the set. Octavo 989 pages, 1224 illustrations General Index to Vols 1 to 6 Octavo 189 pages Phila. and London, W B Saunders Co, 1924 Cloth, \$10 per volume Index volume free. Sold by Subscription only
- HIRSCH'S "COMPEND OF GENITO-URINARY DISEASES AND SYPHILIS,"** Including their Surgery and Treatment. 4th Edition Revised 44 illustrations Cloth, \$2 00 By CHARLES S HIRSCH, M D Urologist to the Jewish Hospital, Mt. Sinai Hospital, and Eagleville Hospital for Consumptives, Out patient Dept., Philadelphia. P Blakiston's Son and Co, Philadelphia, 1924
- MEDICAL EDUCATION, A COMPARATIVE STUDY** By ABRAHAM FLEXNER, The Macmillan Company, 1925 Price, \$2 50
- PROCEEDINGS OF THE INTERNATIONAL CONFERENCE ON HEALTH PROBLEMS IN TROPICAL AMERICA.** Held at Kingston, Jamaica, B W I, July 22 to August 1, 1924 By Invitation of the Medical Department United Fruit Company Published by United Fruit Company, Boston, Mass., 1924
- HANDBOOK OF OPERATIVE SURGERY** By SIR WILLIAM IELAND DE C WHEELER, (Mod) B A., M D (Dub Univ), F.R.C.S.I., F.A.C.S. (Hon.) Surgeon to Mercer's Hospital and the National Children's Hospital, Dublin Fourth Edition, William Wood & Company, New York, 1925 Price, \$5 50
- THE PRACTICAL MEDICINE SERIES,** comprising eight volumes on the year's progress in medicine and surgery Vol IV, Pediatrics, edited by ISAAC A ABT, with the collaboration of JOHANNA HEUMANN, M D Series 1924 The Year Book Publishers, Chicago, Ill Price, \$2.00
- HANDBOOK OF BACTERIOLOGY** For Students and Practitioners of Medicine By JOSEPH W BIGGER, M D (Dublin), F.R.C.P.I., D P H., William Wood & Company, New York, 1925 Price, \$5 00
- DIABETIC DIET** A Handbook for Diabetics By A DORIS MCHENRY, B A., and MARJORIE M COOPER, B A Harper & Brothers, New York
- SELECTED MEDICAL PAPERS,** containing eighteen articles reprinted from the writings of Dr ALFRED WORCESTER, one article from the writings of Dr EDWARD R. CURLER, and four sketches by Mr RUSSELL T HYDE. The Four Seas Company, Boston 1925 Net, \$3 00
- AN INTRODUCTION TO PRACTICAL BACTERIOLOGY, AS APPLIED TO MEDICINE AND PUBLIC HEALTH** A Guide to Bacteriological Laboratory work for Students and Practitioners of Medicine. By T J MACHIE, M D, and J E. MCCARTNEY, M D William Wood & Company, New York. Price, \$3 50
- DISEASES OF THE RECTUM AND PELVIC COLON** By MARTIN L. BODKIN, M D, F.A.C.S., New York. Illustrated. Second Edition Revised and Enlarged E B Treat & Company, New York, 1925 Price, \$6.00
- THE TECHNIC OF LOCAL ANESTHESIA** By ARTHUR E. HERTZLER, A.M., M.D., Ph.D., LL.D. F.A.C.S. Third Edition. With 140 Illustrations The C. V Mosby Company, St. Louis, 1925 Price, \$5.50
- ON THE BREAST** By DUNCAN C. L. FITZWILLIAMS C.M.G., M.D., Ch.M., F.R.C.S., Ed and Eng C V Mosby Company, St. Louis, 1924 Price, \$10 00

## DISEASES AND FATE OF TWINS \*

By ISAAC A ABT, M D,

CHICAGO, ILL.

IT is with the modern biological, rather than with an anthropological study of twins that the present paper is concerned Grassl<sup>1</sup> expresses the opinion that multiple pregnancies are neither atavistic nor the result of variation, but simply indicate an excess of the natural or usual fertility He attempts to confirm this opinion by his experience obtained by collecting hazel nuts for a period of thirty years When the season is favorable and the crop is unusually good, double ones occur with greater frequency than in those years when the productivity of the bushes is small He found the same true of dandelions In those seasons when dandelions are abundant, double flowers are of common occurrence.

It has also been maintained that climate, race, and the age of mother or father influence the birth of twins Bruder<sup>2</sup> found that twins from one ovum are usually born of women under twenty-five years of age, twins from two ova of women over twenty-five Primipara are more likely to have one ovum than two ovum twins In every age of development one ovum twins are weaker than those from two ova because obviously one placenta cannot sufficiently nourish two fetuses

Two kinds of twins are distinguished those that originate from a single ovum, and those that originate from two separate and distinct eggs Two ova escaping from an ovary at the same time may be fertilized and ultimately develop into two distinct fetuses in the uterus If the ova locate in close proximity, the two placentas fuse, but their circulatory mechanism does not If the two ova locate at a considerable distance from one another two distinct placentas are formed Where the twins originate from one ovum—so-called homologous or monochorionic or identical twins—it is assumed that two polar bodies must be extruded

The placenta in uni-oval twins is always sin-

gle. There are usually two cords, though occasionally there is only one which bifurcates near the body of the fetuses One egg twins are relatively rare Ahlfeld<sup>3</sup> found in 1,157 twin pregnancies only 15.55 per cent that were uni-oval While proof is lacking, nevertheless there are those who think that fecundity and a tendency to bear twins or triplets are inherited

It is also maintained that there are racial differences in the frequency of twin births For example, twin births occur more frequently in the Slavic, Hungarian, Finnic, and Germanic races It is said that twin pregnancies are rare among Latin races, and that they occur less commonly in Japan than in Europe In 1,339,975 births in the United States in 1917 there were 1 in 931 twins Statistics gathered from all parts of the world seem to indicate that on the average sixty-three per cent are of the same sex, thirty-seven per cent of the opposite sex

A Orgler<sup>4</sup> recorded some observations on twins from his examination of twenty-six pairs The weight was the same in only five pairs The difference in weight was more marked when the twins were of different sex They usually increased in weight at the same rate, though frequently one continued to be heavier than the other for a considerable time, unless one or the other fell ill He also observed that if both twins fell ill, one of them usually lost more markedly in weight than the other, and when they regained health, both increased in weight at the same rate, though the original disproportion continued for some time

In a number of cases the heavier child is more resistant and becomes less severely ill when attacked than the lighter one In a number of cases this does not hold Frequently there is a difference in the length of the children at birth While many of them seem to increase at the same rate, in a certain number the increase in length occurs at different rates, so that the one shorter at birth may reach the height of the longer one or even overtake him

\* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester April 23 1924

The average weight of twins is approximately equal to the weight of a single newborn. The average weight of uni-sexual twins was 3,960 grams, though the female pair weighed 840 grams less than the male. The average weight of the male pairs was 4,380 grams, of female pairs 3,540 grams, and the average weight of one twin was 1,980 grams, though there was a difference in the weight of the sexes. Thus, boys weighed on the average 2,190 grams, girls 1,770 grams.

Concerning the height of newborn twins, it may be noted according to the statistics of N. Miller<sup>5</sup> that the average length was 43 cm and that the girls averaged 3 cm less than the boys. The average height of boys was 45.5 cm, that of girls 41.5 cm. Newborn twins, especially those of the same sex, may be approximately of the same height and weight.

On the other hand, there may be great disparity in their weights, varying from 200 to 800 grams and, in extreme cases, even 1,000 grams. Differences in height are also noted. Sometimes one infant is 2.5 cm longer than his mate.

Differences in the development may be accounted for at times on a purely mechanical basis. In some instances the nutrition of the two fetuses is unequal. In one case the umbilical cord may be short and straight, in the other one, long and winding. It is evident that in the former the blood supply would be greater and the nutrition would be better. At other times, one placenta is located favorably on the uterine wall, and the other one is attached in an unfavorable position. The greater the respiratory surface of the placenta, the better the fetus develops. In other words, the larger the placenta the more closely it is approximated to the uterine decidua, and the more favorable are the conditions of the fetus.

Newman<sup>6</sup> states in his "Physiology of Twinning" that there is a popular impression that in human twins one is usually stronger and more vigorous than the other. Practical experience tends to bear out this impression. Even in identical twins, there is usually a more vigorous twin who is the dominant member of the combination. One twin tends to gain a physiological ascendancy over the other to the slight or very great detriment of the latter. Spaeth<sup>7</sup> found no evidence that the twins of either type had any definite physiological effect upon each other, though he grants as an evidence of inter-influence the condition of *situs inversus viscerum*. Newman<sup>6</sup> points out the disadvantages of twinning by saying that when two or more fetuses come to occupy the space usually filled by one, the twins, whether of the one egg or two egg type, crowd each other and compete for the common food supply. In the case of two egg twins, the competition is for placental surface.

The period of uterine gestation is at best a

hazardous one. In addition to those hazards that are met by single embryos and by two egg twins, there are certain very serious special dangers that fall upon one egg twins by reason of their close genetic relationship. One egg twin varies according to the period when the placenta is developed, and consequently one may receive more nutriment than the other. Moreover, on account of the difference in the blood supply to the two fetuses, one is more favored than the other, a condition which may even lead to the death of the less favored. Because of these variations in food supply and as a result of one fetus crowding upon the other, there is not only a disproportion in size and weight of the two infants, but malformation and conditions of arrested development may be noted in the weaker twin. Thus, one of the pair may be strong and healthy at birth, the other weak and delicate physically and defective mentally.

In my practice I have such an instance. The weaker one was extremely difficult to nourish, was very much retarded physically, and has remained defective mentally, while the other child developed rapidly and normally. The twins are now fifteen years old, the one a tall, bright, well-developed girl, while her sister is infantile in size and has attained no mental development. I recently saw a pair of male twins, three years old. One was bright, well grown, and his development was perfectly normal. The other weighed only twenty pounds at three years, teeth developed late, and his static development was markedly delayed. He was mentally much retarded and unable to talk. The normal twin's birth weight was six pounds, the other's three pounds. Instances of this kind must be very frequent.

Dentition may occur at different periods in the two infants, and this does not always depend on the severity of the rickets. In one pair that seemed free from rickets, the first dentition occurred at the seventh month, while the other infant developed his first teeth two months later. At ten months the first infant had eight teeth, while the other had only two. The difference between the eruption of teeth in the two babies may be as long as four months.

Francis Galton<sup>8</sup> made a study of twins from the biologic and genetic aspects, and hoped to be able to differentiate between the effects of tendencies received at birth and of those that were imposed by the special circumstances of their afterlives. He sent questionnaires to persons who were either twins or near relatives of them. He received eighty replies, thirty-five of which entered into instructive details. In a few of these not a single point of difference could be specified. The color of the hair and the eyes was almost always identical. In many instances the twins were of the same height, weight, and strength. In others there was a notable dif-

terence in these factors, though the resemblance was in other respects close

The manner and personal address of the thirty-five pairs were similar. The speaking voices of twins were usually the same, even where they sang in different keys. The handwriting was usually dissimilar, no matter how much the twins resembled each other. There is, however, one exception to this in Galton's series, where the handwriting was so similar that the two brothers could not distinguish their own lecture notes. In a number of Galton's collected cases, the twins suffered from some special ailment or had some exceptional peculiarity. Thus, several pairs showed peculiarities in their fingers, consisting of a slight congenital flexure of one of the joints of the little fingers. Another pair of twins had crooked little fingers. There were frequently close resemblance and correspondence in the falling of the hair. Several died of the same diseases. Very frequently both fell ill at the same time, not necessarily with contagious diseases. Thus, one parent writes to Galton "If anything ails one of them, identical symptoms nearly always appear in the other." Galton also points to the extreme resemblance and similarity in the ideas and associations of twins. They are inclined to make the same remarks on the same occasions, begin to sing the same songs at the same moment. One would commence a sentence and the other would finish it.

Galton found from his inquiry that while there were many points of resemblance in taste and ideas, there were certain differences which may be represented by the following groups of qualities. The one was vigorous, fearless, energetic, the other was gentle, clinging, timid. Or the one was more ardent, the other more calm and placid. Or again, the one was more independent, original, and self-contained, the other more hasty, generous, and vivacious. The difference was that of intensity rather than energy. It did not involve their fundamental characters. Ill health might depress the more vivacious. Galton says the difference was in the keynote, not in the melody. In the "Comedy of Errors" Shakespeare makes Dromio say, "Methinks you are my glass, and not my brother."

Twins may be dissimilar at birth and tend to become more alike on account of the close relationship in their lives.

Twins may present sharply contrasted characteristics in their physical, as well as in their mental, constitutions. The dissimilarity of twins is illustrated by the story of Esau and Jacob who, as it is recorded, differed even at birth. "The boys grew and Esau was a cunning hunter, dwelling in the fields, and Jacob was a plain man, dwelling in the tents." As they grew older, Esau became a hairy man and Jacob had a smooth skin. The dissimilarity at birth con-

tinues more or less throughout life, no matter how close the association or how similar the training.

Even joined twins may show striking dissimilarity. This is illustrated in the famous Hungarian joined twins, Judith and Helen. Judith was homely, nervous, hypochondriacal. Helen was pretty, healthy, with a happy disposition. Judith suffered frequently from neuralgia and convulsions, while Helen remained healthy except for an attack of pleurisy. Menstruation occurred at different periods.

The Siamese twins also showed dissimilarity in characteristics. They married at the age of thirty-two and between them had twenty-two children. Cheng was weaker and of an equable temperament, Eng was stronger, though inclined to be melancholy. The brothers often quarrelled. This occurred most often if one of them imbibed too freely. Finally Cheng developed hemiplegia which was followed by pneumonia of which he died. Eng witnessed the tragedy of his brother and asked to be released. The operation was performed at his request, and his death occurred two hours after the death of his brother.

Gesell<sup>9</sup> reports twins who showed superior intellect. They both sat up at six months, walked and talked at eleven months, learned French at three years, and were in the seventh grade at the age of nine. They resembled one another, both physically and mentally. In fact, there was no noteworthy distinction between the two. Their physique, countenance, demeanor, conversation were completely similar.

Homologous twins usually show marked similarity physically, as well as mentally. They resemble each other in weight, body structure, voice and gait. They may learn to speak and walk at the same time. Not rarely they show the same anomalies and faults of development. They may become sick at the same time and die almost at the same time.

Ganther and Rominger<sup>10</sup> studied the finger prints of five pairs of one ovum twins and forty-two pairs of two ovum twins. They found that in the five pairs of one ovum twins there was marked similarity in the finger prints, and in the system of lines of the hands. In the two ovum twins there is a certain similarity of structure, but never the striking correspondence of the system of lines. They conclude from their studies that a striking similarity of the structure of the lines of the hands indicates that the twins are uni-ovular. H. Wilder,<sup>11</sup> in *Science*, 1909, also concluded that finger and sole prints which are identical or nearly so, indicate single ovum twins.

Ahlfeld<sup>3</sup> collected seven cases of similar malformations in homologous twins. Others have observed patients in which both had pseudo-hermaphroditism. D'Outrepoint reports a case in which both twins had spina bifida. According to Siebold and Velpeau<sup>12</sup> both twins had six fin-

gers Lehmann<sup>12</sup> writes of twins with cerebral hernia and hypospadias

Miller<sup>5</sup> describes 247 pairs of twins of the same sex which he studied at the Moscow Findelhaus. He assumed that thirty were homologous. Twenty-three showed similar or analogous malformations. In five pairs the twins had hypertrophied umbilicus. Four had dolicocephalic skulls and four others congenital phimosis. Two had congenital depressions of the sternum. Two other pairs had marked shortness of the frenulum of the tongue.

Some of the twins showed anomalies occurring in both during the early days of life as a result of acquired disease. Thus, two boys had simple pemphigus. Two other male twins both developed mastitis on the left side, followed by erysipelas. They both recovered practically at the same time.

Brophy<sup>13</sup> quotes a paper by Albert D. Davis, of Omaha, on twins having congenital cleft lip and palate. In six twins one of each pair had cleft palate. Shearer<sup>14</sup> reported three cases of cleft palate in twins in one of which both girls had cleft palates. One had a cleft lip on the right side, the other on the left.

Among the rare conditions may be mentioned a case of congenital megacolon in one of twins. H. Goldstein and M. Schenck<sup>15</sup> contributed a description of an unusual case of dwarfism in twins. These were seven years old. The smaller one showed on examination that half of the body was uniformly smaller than the other side. The smaller child was mentally backward. Harrison<sup>16</sup> reported in the Virginia Medical Monthly, 1919, one of twins with congenital absence of the right femur.

The temperature of twins sometimes varies at birth. One infant may show two to three-tenths of a degree higher temperature than the other. As a general rule, well-developed twins have a slightly higher temperature than those who are weakly.

**Prematurity.** Twin pregnancy is a relatively frequent cause of premature birth. Ylppö's<sup>17</sup> series of prematurity showed that out of 688 cases, 19.2 per cent, or 128 cases, were twin babies.

The prematurely born, whether singly or in pairs, are predisposed to a variety of disorders. The susceptibility of prematures to rickets is a common observation. Huenekens<sup>18</sup> found that of seventy cases of premature twins, fifty-eight developed definite signs of rickets. He observed that the condition appeared sometimes before the fourth month of life. Craniotabes, an early symptom, may be present in the sixth week of life.

Other rachitic manifestations occur in premature twins as well as in prematures of single birth. Among the early symptoms may be mentioned rachitic rosary and rickets of the long cylindrical bones. In premature infants there is a deficiency of the calcium content as well as

of other mineral substances. By the third or fourth month, there is a lowered phosphorus and calcium content, and rickets and its sequelæ result.

Premature or underweight newborn twins frequently manifest the spasmophilic diathesis and tetany. Evidence of spasmophilia may be found in these infants even if they are born at full term.

An instance is cited where, in a pair of twins, the one developed laryngismus stridulus, facial phenomenon, and electrical over-excitability, giving all the symptoms of spasmophilia, while the other remained free from this disorder. It has also been observed that craniotabes may be present in one infant and absent in the other.

Langstein<sup>19</sup> reports a case of twins in whom convulsions always appeared when artificial food was used as a substitute or complement for breast feeding. It should be noted, however, that the twins did not develop the tetany at the same time. One pair developed spasmophilia within seven to twelve days after the administration of artificial food, the other eighteen to twenty days thereafter.

A pair of twin girls, nine weeks old, came into my service on the 19th of July, 1922. The first one had convulsions lasting three days. The other twin had convulsions which lasted a week. They both had marked craniotabes, Harrison's groove, slight rosary, and protuberant abdomen. The Chvostek sign, as well as carpopedal spasm, were present in both. Both were breast fed. Thus, it is evident that these nine weeks old infants had almost similar attacks of tetany with florid rickets.

In twins not prematurely born, rickets and spasmophilia in both children is a frequent occurrence and is commonly observed. Orgler<sup>4</sup> records in his series a case of rachitic twins where the degree of intensity was different. The one was severely affected, the other only moderately. He also recorded a case in which one child had developed scurvy, the other had not. Alfred Hess<sup>20</sup> says that twins have a special tendency to develop rickets, and this is partly due to a sub-normal quota of anti-rachitic constituents stored in their tissues and also to the variable susceptibility of infants to rickets.

**Anemia.** The anemias of prematures may be of a high degree and may be prolonged into the second and third year, though this condition may occur in children born at term.

A pathological anemia occurring in twins may affect one or both. The hemoglobin is usually low and the reduction may be observed during the first days of life. Occasionally one or both parents show marked debility or anemia. Charles Herrman<sup>21</sup> states that twins and single infants born prematurely come into the world with an imperfectly developed blood forming system and, if some injurious external agent affects the in-

tants, this latent inferiority soon manifests itself. He says that some of these infants show their anemia from birth, some not until later. Von Jaksch's pseudo-leukemic anemia may occur in one or both twins. Finkelstein<sup>22</sup> reports twins who developed a clinical type of pseudo-leukemic anemia after infections.

Chlorotic anemia has been described from Finkelstein's clinic by Kunkel as occurring in prematures and twins. Kunkel's investigations considered the blood changes in premature and feeble children. Among this group were seven pairs of twins, sixty prematures, seven feeble children. He found that most of them suffered from a chlorotic type of anemia characterized by oligosideremia and slight diminution of the cellular elements of the blood. Spleen and lymph nodes are not enlarged. This form of anemia occurs very early in life. This is particularly true of the prematures. Kunkel gives several instances where the twins were much below normal in weight and the anemia continued until one infant was four months old. At that time his hemoglobin was 43 per cent. When the children were taken out of doors, the condition improved, though at the sixth month the hemoglobin content had reached only 60 percent. Occasionally only one of the infants becomes anemic, though as a rule both are affected, but there may be a difference in degree. Senator reported a case of splenic leukemia which developed in twin sisters of eighteen months. Both died about the same time.

**Mental Affections.** Mongolian idiocy may occur in one or both twins, though in the majority of the cases only one of the pair is affected. Halbertsma<sup>23</sup> quotes sixteen instances where one of the twins was a mongol and two where both were mongols. His table is appended (Insert I).

The mental affections of twins do not differ

in form or in frequency from those of other individuals. A limited number of psychic disturbances have been reported which do not differ from those encountered in children of single birth.

Epilepsy of both children with mental deficiency is reported. A few cases of dementia precox have been recorded. Hydrocephalus occurred in a pair of twins. One was delivered by craniotomy, the other was born spontaneously. There was no syphilis or alcoholism in the parents. The father was by occupation a painter, but did not suffer from lead poisoning. The second infant died on the twelfth day.

Soukhanoff<sup>24</sup> made an analysis of thirty-three cases of insanity in twins in 1900. In some there were congenital mental defects, in one dementia precox, in one general paralysis. In most cases the twins uni-ovular, alike in appearance and mental character, and the form of insanity in each pair was the same.

Schütz and Ostermayer<sup>25</sup> state that the cause of psychosis lies in a high grade similarity in the structure of the brain, so that the psychic functions show a parallelism both physiologically and pathologically. Ostermayer collected fifteen cases from the literature. Duncan Campbell<sup>26</sup> found twenty-nine cases of insanity in twins. Among those described are maniac depressive insanity, melancholia, paranoia, dementia precox, imbecility, and idiocy. In several of the cases which he reported the twins were living in different cities, but the disease occurred at the same time and apparently in the same manner. Elmgier<sup>27</sup> believes that the psychoses in twins must be regarded in the same way as are psychoses in siblings. Mental deterioration is not peculiar to twins but merely indicates that they are of the same constitution and predisposed to

#### CASES OF MONGOLISM IN ONE OF TWINS

No	Author	Sex of Twins	Type of Twin
1	Fraser ( <i>J Ment Sc</i> , 1877)	The mongol was one of twins	Unknown

2	De Bruin ( <i>Nederlandsch Tijdschr v Geneesk</i> 1902)	Two mongol boys	One egg (?)

gers Lehmann<sup>12</sup> writes of twins with cerebral hernia and hypospadias

Miller<sup>5</sup> describes 247 pairs of twins of the same sex which he studied at the Moscow Findelhaus. He assumed that thirty were homologous. Twenty-three showed similar or analogous malformations. In five pairs the twins had hypertrophic umbilicus. Four had dolicocephalic skulls and four others congenital phimosis. Two had congenital depressions of the sternum. Two other pairs had marked shortness of the frenulum of the tongue.

Some of the twins showed anomalies occurring in both during the early days of life as a result of acquired disease. Thus, two boys had simple pemphigus. Two other male twins both developed mastitis on the left side, followed by erysipelas. They both recovered practically at the same time.

Brophy<sup>13</sup> quotes a paper by Albert D. Davis, of Omaha, on twins having congenital cleft lip and palate. In six twins one of each pair had cleft palate. Shearer<sup>14</sup> reported three cases of cleft palate in twins in one of which both girls had cleft palates. One had a cleft lip on the right side, the other on the left.

Among the rare conditions may be mentioned a case of congenital megacolon in one of twins H. Goldstein and M. Schenck<sup>15</sup> contributed a description of an unusual case of dwarfism in twins. These were seven years old. The smaller one showed on examination that half of the body was uniformly smaller than the other side. The smaller child was mentally backward. Harrison<sup>16</sup> reported in the Virginia Medical Monthly, 1919, one of twins with congenital absence of the right femur.

The temperature of twins sometimes varies at birth. One infant may show two to three-tenths of a degree higher temperature than the other. As a general rule, well-developed twins have a slightly higher temperature than those who are weakly.

**Prematurity.** Twin pregnancy is a relatively frequent cause of premature birth. Ylppö's<sup>17</sup> series of prematurity showed that out of 688 cases, 19.2 per cent, or 128 cases, were twin babies.

The prematurely born, whether singly or in pairs, are predisposed to a variety of disorders. The susceptibility of prematures to rickets is a common observation. Huenekens<sup>18</sup> found that of seventy cases of premature twins, fifty-eight developed definite signs of rickets. He observed that the condition appeared sometimes before the fourth month of life. Craniotabes, an early symptom, may be present in the sixth week of life.

Other rachitic manifestations occur in premature twins as well as in prematures of single birth. Among the early symptoms may be mentioned rachitic rosary and rickets of the long cylindrical bones. In premature infants there is a deficiency of the calcium content as well as

of other mineral substances. By the third or fourth month, there is a lowered phosphorus and calcium content, and rickets and its sequelae result.

Premature or underweight newborn twins frequently manifest the spasmophilic diathesis and tetany. Evidence of spasmophilia may be found in these infants even if they are born at full term.

An instance is cited where, in a pair of twins, the one developed laryngismus stridulus, facial phenomenon, and electrical over-excitability, giving all the symptoms of spasmophilia, while the other remained free from this disorder. It has also been observed that craniotabes may be present in one infant and absent in the other.

Langstein<sup>19</sup> reports a case of twins in whom convulsions always appeared when artificial food was used as a substitute or complement for breast feeding. It should be noted, however, that the twins did not develop the tetany at the same time. One pair developed spasmophilia within seven to twelve days after the administration of artificial food, the other eighteen to twenty days thereafter.

A pair of twin girls, nine weeks old, came into my service on the 19th of July, 1922. The first one had convulsions lasting three days. The other twin had convulsions which lasted a week. They both had marked craniotabes, Harrison's groove, slight rosary, and protuberant abdomen. The Chvostek sign, as well as carpopedal spasm, were present in both. Both were breast fed. Thus, it is evident that these nine weeks old infants had almost similar attacks of tetany with florid rickets.

In twins not prematurely born, rickets and spasmophilia in both children is a frequent occurrence and is commonly observed. Orgler<sup>4</sup> records in his series a case of rachitic twins where the degree of intensity was different. The one was severely affected, the other only moderately. He also recorded a case in which one child had developed scurvy, the other had not. Alfred Hess<sup>20</sup> says that twins have a special tendency to develop rickets, and this is partly due to a sub-normal quota of anti-rachitic constituents stored in their tissues and also to the variable susceptibility of infants to rickets.

**Anemia.** The anemias of prematures may be of a high degree and may be prolonged into the second and third year, though this condition may occur in children born at term.

A pathological anemia occurring in twins may affect one or both. The hemoglobin is usually low and the reduction may be observed during the first days of life. Occasionally one or both parents show marked debility or anemia. Charles Herrman<sup>21</sup> states that twins and single infants born prematurely come into the world with an imperfectly developed blood forming system and, if some injurious external agent affects the in-

pemphigus, eczema and the so-called exudative diathesis are not infrequently recorded, but differ in no way from the same affections when they occur in other children. There is recorded a case of eczema in one twin, while the other was free from the affection, at least during the time when they were both examined. Kretschmer<sup>26</sup> reports twin girls, fourteen years of age, who entered the hospital at the same time, both of whom showed renal tuberculosis. Worcester<sup>27</sup> reported phthisis occurring at the same time in both children.

**Mortality.** Twins in general are characterized by low vitality. The death rate is much greater than in single newborns. In the first weeks after birth the mortality is forty per cent. It is generally stated that twins have thirteen times less chance to live than ordinary newborn babies. In the report of Miller's<sup>5</sup> cases at the Moscow infant Asylum 3,883 pairs of twins were observed among 277,902 children. 62.9 per cent of these died during the first weeks of life. In half of the cases, both twins died on the same day. In the remainder, the one lived one or two days longer. Septicemia and syphilis were frequent causes of death. The greatest mortality of those infants who survived the first few weeks of life seems to concentrate in the first and second year. After the fifth year of life, the mortality of twins and non-twins is about the same.

It has been estimated that out of a hundred pairs of twins born there are eighty pairs who survive. In fifteen pairs, only one child survives, in five pairs both children die. According to Hecker,<sup>28</sup> fifteen per cent die during the first eight days. It has also been said that twin girls seem to have greater viability than twin boys.

Since Galton's memorable studies no investigation has been conducted on the pathological aspect of twins. The *British Medical Journal* of 1912 contained a very interesting and suggestive editorial on twinship and fame. The editorial was suggested by the remarks of Doctor Kaiser, of Dresden, who stated that he knew of no famous man who had a twin brother. A similar query had been raised by Doctor Simpson in the *Edinburgh Medical Journal* of 1862. Simpson was not aware of a single instance in which a twin had distinguished himself intellectually. The editorial writer takes issue with these two gentlemen and goes on to show that there were several twin brothers who had won more or less fame. In attempting to collect information on this subject, it was found that no records of morbidity or mortality in twins were available.

It is to be regretted that there are not more data at hand concerning the development, physical and mental of twins during their later lives. To make such data available, it would be important for obstetricians to record in every instance whether the twins originated from one or two eggs, which information should also be

supplied to the families. Parents, physicians, teachers should be able to furnish significant information. Twins themselves or their friends might in some instances contribute important biographical sketches, and life insurance companies and bureaus of vital statistics should furnish details about the causes of death. Information of this kind would be of great interest, if not of practical value, to a great number of people. Knowledge of such facts would constitute a noteworthy contribution to medical science.

the same hereditary disorders. Migraine has been observed in both twins.

J. H. Hess<sup>28</sup> reports Friedreich's ataxia in twin brothers, age ten years. This condition followed an acute infectious disease when they were eight years. The affection had been progressive in both boys, the one showing less involvement than the other. Family history was negative. The disorders from which these boys suffered consisted of a mask-like face, tremor of the tongue, scoliosis, poor muscular development, awkward, staggering gait, slow, scanning speech, defective memory. The Romberg and Babinski signs were positive. One year later the defective gait was more pronounced. Horizontal nystagmus was present. The arches of the feet were very high. The author makes some reservation about the diagnosis, and considers the possibility of a post-infectious encephalitis, as well as that of a multiple sclerosis.

**Infections.** According to Orgler's observations, the behavior of twins towards infectious and nutritional disturbances was not always the same in both. One twin became ill with bronchitis, while the other developed whooping cough. The first recovered in two weeks, while the latter remained ill for two months.

They often reacted differently to infectious diseases. One twin died of generalized military tuberculosis, while his mate developed tubercles and a strongly positive Pirquet reaction and the disease ran a more protracted course. In those instances where one twin developed rickets or exudative diathesis, the other had it also, though the intensity of the manifestations was frequently variable, the disease being intense in one child, mild in the other.

There is also recorded a case of single ovum twins who seemed to be similar physically and mentally, but who showed some difference in their resistance to infection. Whether this difference in resistance is peculiar to one ovum twins cannot be definitely stated. It may be assumed that there has been an unequal division of the germ plasma in the uniovular variety which might account for the variable behavior to infection.

Three sets of double ovum twins, observed by Orgler, showed uniform behavior to infection. However, in the case of twins of opposite sex who were admitted to the hospital at the age of five weeks and remained there for a considerable length of time, the boy, at the age of six months, developed measles, while the girl remained free from the disease, notwithstanding the fact that they occupied adjoining cribs.

Ballantyne<sup>29</sup> in his "Antenatal Pathology" records a case where both twins acquired variola from their mother. In another case, one was affected while the other escaped. In a third, both fetuses exhibited the eruption. One presented many pustules, while the other had only a few.

During infancy and early childhood twins, like other siblings, develop almost simultaneously intestinal upsets, grippal infections, measles, mumps, chicken pox, scarlet fever, and other infections.

**Syphilis.** Where one or both parents are syphilitic, the twins, as a rule, suffer the same fate as does the fetus in a single pregnancy. There are cases recorded, however, where one of the twins presents evidence of manifest lues while the other seems to remain immune. Grete Singer<sup>30</sup> reports twins, a girl and a boy, one of whom was clinically and serologically luetic, the other normal. The non-infected infant showed negative Wassermann reactions during a period of two years. Finger<sup>31</sup> reports cases of dissimilar severity of syphilis in twins, i. e., one was more severely affected than the other. There are numerous corroborative reports in the literature, in which one case was syphilitic, the other healthy. Rosinski<sup>32</sup> reported syphilis in twins. The boys showed severe symptoms of hereditary lues. The girl, who was observed for twenty-four years, remained entirely free from the disease. No satisfactory explanation can be found for this inequality in the distribution of the disease. Why one child should be infected and the other remain free is difficult to conceive. It has been suggested, however, that the difference in the severity of the disease is due to different modes of infection. It is thought that this is more probable than that there is a difference of immunity in the two fetuses.

**Miscellaneous Diseases.** In Ballantyne's<sup>29</sup> "Antenatal Pathology and Hygiene" a case of Stocker is quoted. A woman had eleven children, including one set of triplets and two sets of twins. The twins under consideration were female, one of whom was a giant infant. She menstruated at three years of age, and when eight had the appearance of a girl of twelve, measuring 139 cm in height and having well-developed genitals and mammae. The other girl developed normally.

Sclerema neonatorum may occur in one or both twins. Northrup<sup>33</sup> reports sclerema in one such. Carminati<sup>34</sup> states that the disease is especially common. Ichthyosis may be a familial disease, attacking several children of the same family. Ballantyne reports a woman who gave birth to twins, one of whom suffered from ichthyosis. There are a few cases recorded in Tarnier Budin's<sup>35</sup> textbook of midwifery in which one of the twins suffered from general dropsy. One fetus was affected with general dropsy. There were two distinct amniotic sacs. The membrane of the edematous fetus were infiltrated with serum. In every case the dropsical fetus was still born, while the other twin was viable and unaffected by this disorder. Galton<sup>8</sup> reports a case in which both grown-up twins developed Bright's disease at the same time. Cases of

## FOOT STRAIN \*

By SAMUEL W BOORSTEIN, M D, F A C S,

NEW YORK CITY

IN selecting a topic for this gathering none appealed to me so much as "Foot Strain," since almost every civilized person, and especially the city dweller, is subject to this affliction. Hence, this is a more or less vital topic to everyone. The medical men of your organization have to know more about foot disturbance than formerly, as their patients demand more information. Even if they do not attempt to treat them themselves, they must be able to answer the questions they are so often pried with.

You dentists and pharmacists, having to stand on your feet a great deal, ought certainly to be interested in this topic. The Northern Dental Society considered this topic sufficiently important to invite me to read before them a paper which was afterwards published in their journal under the title "The Efficiency of the Dentist as Affected by Weak Feet."

The members of the legal profession feel the effect of foot strain and transmit it to their work.

Not only you, yourselves, but almost every member of your family, including the children, suffer from such afflictions.

This affection is so widespread that during the recent war many men had to be rejected from the army on account of their weak feet. This number was so great that at the second draft they had to be accepted, and afterwards constituted one of the greatest problems for the orthopedic surgeons. Special squads were instituted, but the problem was never solved.

Medical literature on the topic is voluminous. The shoe stores with their expert advertisers have spread both proper and improper information in attempts to interest the public in their particular shoe. It is no exaggeration to say that 60 to 70 per cent of the urban population is suffering from some foot trouble, and about 60 per cent of those consulting the orthopedic surgeon are afflicted with "Foot Strain," and not with rheumatism as they themselves imagine.\* So much

has been written about shoes and plates as to cause a great confusion and leave one at a loss as to which procedure to follow. I will here attempt to bring some order out of this chaos, by giving you a more definite idea about normal and abnormal feet, foot strain, and shoe wear.

### ANATOMICAL CONSIDERATION

I will take just a few minutes to give a short resume of the anatomy and function of the foot.

Mechanically, the foot is an elastic arched structure, bearing the body weight, and it articulates with the bones of the leg at about the posterior third of the foot. The functions of the foot are (1) weight bearing, and (2) propulsion. It must be remembered that in standing as well as walking or running, the entire weight of the body is transmitted to the ground by way of the astragalus, which is the only foot bone in contact with the leg bones.

*The Arches*—The foot has two arches, the longitudinal, and the transverse or anterior arch. The longitudinal arch or instep forms a half dome, and when the two feet are placed close to each other they form a dome, not circular, but elliptical in shape. The dome formed by the two feet rests on the ground all around the edge from the heel of one foot round the outer border of the foot along the toes and back along the outer border of the other foot to the heel. Considering one foot by itself, the weight of the body rests upon a half dome touching the ground on its outer border. It is stable if the body weight is so balanced that it rests on its outer edge, but if the body weight falls too near the inner side of the half dome there is a tendency for it to capsize inward.

The two arches should be considered as an integral part of one structure and an affection of the longitudinal arch is associated with a disturbance of the transverse arch.

*Improper Posture*—One means of making the leverage function difficult is the custom of turning the feet outward. In this position the strain falls too much upon the inner border of the foot.

In proper walk the feet should be held practically parallel to one another, so that the line of weight passing downward through the center of

\*Read before the Westchester Professional Men's Club November 12 1924

†To be exact I like to quote my statistics. (1) Fordham Clinic for a period of ten years—26% of the new admissions consulted for foot strain. (2) In private practice for the same period—30%. (3) Bellevue Clinic in the last year—48%. (4) Union Health Center for the last three years—85%. The reason why the per cent is so low in Fordham Hospital is because there are many children admitted.

### DIRECT CAUSES

1 Change of occupation requiring longer hours than the patient was previously accustomed to, especially prevalent in cases where a change from inactive to active life takes place. This is very commonly seen among the young girls who take up nursing following their college training. The sudden change from sedentary occupations to standing on the tile floors in the hospitals causes severe foot strain so that during their probationary period they are often forced to consult the orthopedic surgeon. In some hospitals the orthopedic surgeons have instituted the custom of examining the feet of the nurse candidate. Those found having weak feet are dissuaded from taking up nursing. Others who are on the border line are watched during the probationary period and have corrective exercises ordered regularly. If their feet become worse they are not accepted for nursing.

I have been connected for more than ten years with Fordham Hospital and have had a chance to watch the change of occupation from a different view point. Fordham Hospital has no training school for nurses, but gets its nurses through affiliations with other hospitals. Naturally it gets the force from small hospitals that lack the facilities offered by larger institutions. Every time a new batch of nurses comes, at least 25 per cent of them are referred to me as patients within the first month. They invariably suffer from foot strain due to the change to tile floors and more strenuous work.

2 Overuse of the feet in standing and walking. This is especially true in the case of men engaged in sedentary occupations throughout the week and who indulge in long walks on Saturday and Sunday. The foot should be gradually accustomed to exercises. The same condition is seen in naturally athletic young men and women, who, due to their occupation, have acquired sedentary habits, but who play indoor tennis or basket ball on hardwood or cement floors once or twice a week in soft soled shoes.

3 General weakness following an illness or after child birth. To emphasize the causes of flat feet, I recapitulate some of my previous statements. The disability of weak feet is due to a disproportion between the strength of the foot and the weight and strain to which it is subjected. The most constant predisposing cause is the direct injury caused by improper shoes, occupation requiring long hours or standing or

walking, excessive weight and diminution of muscular and ligamentous strength. The direct causes are sudden change of occupation or overuse of the feet on days of rest.

### SYMPTOMS

In general one must remember that a normally high arch beginning to suffer strain, is vastly more painful and more troublesome than an arch in reality much lower but normal for that individual. A high arch is slightly less enduring than any other form of foot—hence one not acquainted with these conditions will neglect to treat the high arch till the ailment is advanced. Abducted and everted foot, and the foot with a notably short tendo-achillis are probably more liable to painful strain under unfavorable conditions than are the other types.

1 Initial symptoms of foot strain usually noticed are that the feet become hot and uncomfortable, burn after use, and perspire more than before.

2 *Weakness and Strains*—The earliest symptom, if patient can recollect, is usually a sensation of weakness, of fatigue and strain about the inner side of the foot and ankle. Sometimes after long standing a dull ache in the calf of the leg, or pain at the knee, hip or the lumbar region (symptoms more common in women than men). Sometimes these symptoms are traced to a certain overexertion, such as a long walk, and thus the victim ascribes the origin of the ailment to such an occurrence. Later on, the patient becomes aware of the fact that he is accommodating his habits to his feet, he rides when he once walked, he sits when he once stood, he no longer runs up or down stairs or jumps off the street car. His feet have lost their spring. The feet stiffen on sitting, and are most uncomfortable on getting up in the morning and at the close of the days work.

3 *Pain*—In the beginning there is discomfort only after standing or walking. Actual pain is felt only when the foot is in use and stops under temporary rest, thus the patient suffers more when he begins to walk after having rested awhile or after rising in the morning. (It is this remittance of symptoms, together with the fact that the discomfort is usually more marked in damp weather that leads so often to the mistaken diagnosis of rheumatism.) In severe cases the pain is continuous.

Pain in the leg, knee, hip or back is frequently complained of. The pain occurring in such a remote region is, due to static disturbances in the flat foot. The pain occurring not directly in the foot, is the stumbling block of the physician. The patient cannot be convinced that the pain in the hip is due to the weak feet and not to rheumatism, sciatica or lumbago, as he had previously been told. Pain is usually found below

\* In some cases where the heel cord is contracted as the result of years of bad shoeing the orthopedist is occasionally compelled to permit a medium sized heel as a low heel will make the patient quite uncomfortable because at every step a special strain is put on the calf muscle, and when the muscle is short and reaches its limit of extensibility the necessary strain in finishing the step must come on the sole of the foot.

the knee and ankle joints, is continued over the second toe

*Art of Walking*—At first one bears the weight momentarily on the heel, then upon its outer border, the heel is then raised and the weight is put on the toes, which have to spread and assist in maintaining equilibrium. The body is then lifted over the tips of the toes. The big toe gives the final push which sends the body further forward.

The movements of the foot are dorsal flexion (bending towards the body) and plantar flexion (bending away from the body), eversion (turning outward), and inversion (turning inward).

*Range of Motion*—Dorsal flexion is ten to twenty degrees less than a right angle. Plantar flexion is fifty to sixty degrees more than right angle. With the knee extended and passive dorsal flexion attempted, the limit of 20 degrees will be found to exist in the minority of cases, and in very many, perhaps the majority of cases, the foot will not go appreciably above a right angle unless it is allowed to evert and abduct.

The muscles which keep up the arch can be developed only by proper use. Weakening of the foot muscles is one of the penalties of civilization, especially since the introduction of railroads, street cars and automobiles. The savages who are barefooted do not suffer from foot strain. Some of them are born with flat feet, but this is normal for them and in motion the foot is kept in a different position.

From the above short remarks on the anatomy it is evident that the weight of the body comes down in the line of gravity through the astragalus to an elastic, weight bearing arch, and is distributed through it to the ground, that the line of gravity comes somewhat to the inside of the center of support and comes upon an arch weaker in its inner component than in its outer.

#### NOMENCLATURE AND DEFINITIONS

The term foot strain has been chosen instead of the commonly abused term flat foot, as the latter is based on the assumption that every case of foot strain is caused by a broken down arch which requires support. And further, it is popularly believed that this condition can be corrected by highly advertised shoes or by the use of plates self exalted in the advertising columns.

The term "foot strain" covers all disabilities of the foot. It may occur in the foot with the high arch as well as in the one where the arch has been flattened.

The term "flat foot" should be reserved for those cases only, where the longitudinal arch of the foot either touches the ground, or where it is so much lowered that it almost touches.

There are other terms used for this condition "weak foot" (Whitman), "pronated foot." The lay people use the term "fallen arches," "broken arches," and "prominent ankles." We will omit all these terms.

#### ETIOLOGY OR CAUSES

Both rich and poor are affected with foot strain. Both sexes seem to be equally attacked. Children are also subject to this ailment.

#### I CAUSES PREDISPOSING TO FOOT STRAIN

1 An occupation which requires continuous standing, hence the ailment is frequently found among waiters, cooks, policemen, letter carriers, cutters, barbers, salesmen, druggists, dentists and nurses. The condition is worse in cases where the work requires standing or walking on concrete or tile floors. The latter is so well-known a source of trouble that in most hospitals it has led to a general reduction of the shift from twelve to eight hours of duty, resulting in an enormous diminution in the amount of trouble encountered.

2 Real organic diseases, as rickets, infantile paralysis, arthritis, and spastic paraplegia.

3 Excessive weight—either through increase of body weight or from habitual lifting or carrying heavy loads, as in the case of men engaged in such work.

4 Diminution in muscular and ligamentous support resulting from ill health or convalescence from illness, especially after a child birth, or rapid growth. This is also found in cases of direct injury to the leg.

5 Lowered resistance which is the result of nervous fatigue and the lack, not the increase of healthy physical exercises.

6 The most common predisposing cause is the wearing of improper shoes. The object of the shoe is to cover and protect the foot and it must therefore, correspond exactly to the shape of the foot. In civilized countries the foot, on the contrary, is encased from early childhood in a more or less unyielding leather shoe. This is invariably narrowed and somewhat pointed in its front part, so that the great toe is displaced outward and cannot grip the ground as it should. As there isn't sufficient room at the toes, the shoe causes crumpling and distortion of the toes and prevents the forward part of the foot from spreading as it should at each step. The sole of the shoe is also more or less unyielding, as a rule stiffened in the shank\* so that the foot is laced down to a stiff sole. This tends to pull down the dorsum of the foot at each step. The heel of the shoe used by the fair sex is very high. This throws the entire weight to the front part of the foot which is unfitted for the burden of the entire body. This is the more ill advised, since the forepart of the shoe is narrow and has no room for even the normal toe. In addition the high heel is frequently the cause of tight heel cord (tendo-achillis) which is too often a con-

\* Some shoe stores point with misplaced pride to the fact that their shoes have stiff shanks.

sidered only preventive and not curative. It will never cure a weak foot.

2 Rest is always necessary for the feet, hence one who has an occupation that compels him to stand on his feet a great deal should rest at intervals (say ten minutes every hour). This will give a fair chance to the tired muscles to rest. In cases of a temporary disproportion as in pregnancy, or after an exhausting disease, it is desirable to rest quite frequently. If the acute foot strain is very tender it may be advisable to confine the patient to bed for 48 hours and order frequent application of hot compresses or foot baths.

3 A weak foot should not be overworked.

4 *Proper Attitude*—One must avoid long continued standing in one position. One should train himself to walk properly, i.e., keeping the feet parallel or even slightly turned in.

5 The proportion of the weight of the body to the foot power should be taken into account, hence it is advisable to avoid overweight and under weight.

One must study carefully the conditions which produced the strain with a view of relieving it.

### *B Treatment of Foot Strain (especially in the flexible foot) I General Principles*

1 Remove or remedy the underlying cause.

2 Correct the abnormal thrust of the line of gravity on the foot so that the weight of the body falls on the foot in a proper relationship.

3 The main aim should be the restoration of function and not merely correcting the deformity.

## II DIRECT TREATMENTS

### 1 *Acute Painful Foot*

*Rest*—Painful, irritable and strained feet, especially, are best treated under rest. If the condition is very bad, staying in bed may be necessary, which is really perfect freedom from all weight bearing. If this cannot be done and if the feet are not too stiff, a good rest can be obtained by strapping the feet with adhesive plaster straps in such a manner as to raise and rest the muscles and ligaments on the under surface of the foot, especially at its inner side. Occasionally felt pads are placed under the strapping.

*Purpose*—The object of strapping the strained foot is to hold it in such a position that those ligaments which are strained and which have been giving trouble on this account are held relaxed, if the foot is at the same time kept at rest, as in recumbency, it is possible to maintain this relaxation by the adhesive strapping. If the foot is used to bear the body weight, this can scarcely be done in the strict sense of the word, it is possible, however, even with the use of the foot, to relieve the ligaments of the stress of weight-bearing to such a degree by means of this strapping that the patient is not only kept free from pain, but the irritation and tenderness at the insertions of the ligaments diminish appreciably. What

is essential to the correct application of this dressing is that one have an understanding of the mechanics of the condition for which it is applied and that each strip of adhesive plaster be applied under tension enough and in such position that it has a real mechanical effect. Thus in the usual case of strained foot, those ligaments are to be relaxed which are strained when the foot acts in its position of functional weakness, since this is abduction and eversion (turned out), the foot must be strapped in such a way that it is held in adduction and inversion (turned in). Furthermore, it is important that the foot be strapped more firmly than is apparently necessary in order to allow for the slipping on the skin which always takes place, and particularly when the foot is used in walking or standing.

Hot foot baths should be used every night. I am accustomed to use epsom salt in the hot water.

When tenderness has passed, exercises should be given to develop power of adduction and inversion of the foot.

### 2 FLEXIBLE FLAT FOOT

The foot is strapped for a while. Then use of supports is indispensable. Such supports are intended for temporary use only. The feet should be strengthened by correct standing, walking, by exercises until the further use of supports becomes unnecessary.

When one advocates plates he encounters great difficulties. The supports that are ordinarily used for flat feet and are sold in the shoe stores do not fulfil the requirements. They are usually ill-fitting and often of such length and shape as to splint the foot and thus to restrict its normal motion. As a rule they are sold by persons wholly ignorant of the first principles of plate requirements. In addition they are often so soft as to bend under use. Ill-fitting plates do a great deal of harm by confusing the soft parts. Almost every person consulting an orthopedic surgeon comes well supplied with plates. The form of the plates really to be recommended, is hard to describe. There are many plates invented by orthopedic surgeons which give excellent results if properly fitted to the proper foot at the proper time. You can, therefore, understand that not every foot can use the same form of plate and, of course, not every orthopedic surgeon recommends the same plate. There are some plates so excellently devised as not only to support the arch, but also to overcorrect the foot, at the same time not preventing the normal motions and thus not to cause atrophy and interfere with the increase of muscular strength.

A great deal has been written against rigid arch supports. One objection is that the wearer becomes dependent upon them, and a second objection is that the continued use may cause atrophy or thinning of the muscles. The prejudice

the internal malleolus and along the ridge of the astragalo-calcaneal joint, and running down on to the inner side of the os-calcis, and in certain cases at the tip of the external malleolus and on the outer side of the os-calcis

4 *Tenderness*—Is usually present in parts of ligamentous strain. It is common under the scaphoid, centre of the heel, behind the internal malleolus, at the outer border of the foot and in the great toe. It is more common in children. The tenderness of the scaphoid is constant.

5 *Muscular Spasm*—Due to irritability and teno synovitis of the muscles, especially of peronei and tibials, also due to irritability of the ligaments caused by the failure of the fatigued and overstrained muscles to reinforce them as they should normally do. This spasm restricts markedly the range of motion of the ankle joint. The tendo-achillis is often considerably contracted.

6 *Stiffness*—Due to congestion and swelling of the foot. It involves mainly the midtarsal joint. The foot becomes so stiff that patient cannot accommodate himself to inequalities of the surface, hence he dreads to cross a rough pavement, for every misstep causes discomfort. At this stage, the patient finds that after sitting or rising in the morning he is unable to walk, but staggers or limps for several minutes (this being explained by local sensitiveness and muscular spasm increased by the use of the limb).

7 *Gait*—Is slouchy, the feet are apparently pushed one by the other or, to use a common expression, the feet are clumsy. The normal raising of the heel is avoided through fear of stress being thrust upon the tarso-metatarsal ligaments. The whole of the foot remains in contact with the floor as the body moves forward.

8 *Condition of Skin*—The foot is usually cold and bathed in perspiration caused by impaired circulation. The return of blood is slow when pressed out of the skin. Local or general swelling appears. The feet feel tight in the shoe. In long continued cases of foot strain a fluctuating swelling, not necessarily painful, develops just in front of and below the external malleolus.

9 *Deformity of the Foot*—The internal malleolus is more prominent than normally and is thought by the patient to have enlarged. The foot is everted (turned out). In many cases, the head of the astragulus and the scaphoid tubercle form a marked bony prominence at the middle of the inner border of the foot.

10. *Pressure symptoms* as callosities under the second and third metatarsal heads, around the heel and inner border of the foot. Tender heel due to periostitis of os-calcis is often present and becomes especially painful when one has to put weight on the flat sole of the shoe. Corns and callosities are marked.

11. Rigid feet are often the result of long continued foot strain. These are persistently held in eversion and deformed position. They are due to marked muscular spasm and secondary bony changes.

*Resumé of Symptoms of Foot Strain*—(1) Indisposition to use the feet as much as formerly, (2) Tiring quickly when walking, (3) Feeling of stiffness while attempting to walk after a rest, (4) Pain when walking or after standing for a while, later continuous pain, (5) Deformed foot (frequently).

#### DIAGNOSIS

The diagnosis of foot strain is not always an easy matter. The first thing to be determined is whether the symptoms are really due to the foot abnormality and not to some other cause. Secondly, what type of foot strain it is, so as to determine what treatments to institute.

#### PROGNOSIS

The prognosis falls under two heads (1) The relief of pain (especially in cases of acute foot strain) and (2) the correction of the existing deformity.

1. As far as relief of pain is concerned, the prognosis is best in people before middle age. If the symptoms are of comparatively recent occurrence due to overuse, bad shoeing, or temporary ill health, the prognosis is better. It is not so good in neurasthenics and overworked women who are obliged to stand on their feet for a long time. In people who are overweight the prognosis is also not so good, unless the weight is reduced.

2. *For the Correction of Deformity*—In normal children the prognosis as to the correction of the deformity is favorable. If they undergo rapid growth or are oversize the progress is somewhat slow.

The results of treatments are as a rule satisfactory. A spontaneous cure is not to be expected. In cases with little permanent distortion, but great muscular weakness, benefit and cure can be expected from careful treatment. In cases of average severity, relief can almost always be given by very simple measures. Severe deformity can be corrected by operative means.

#### TREATMENT

##### *A. Prevention*

1. Proper shoes should be worn by everybody, especially by those who have to stand on their feet a great deal or who have to walk extensively. People who begin to assume an occupation calling for a greater number of hours on their feet, as policemen, firemen, ward tenders, nurses and dentists should especially wear properly fitting shoes at work (perhaps still allowing fashion to dictate the evening shoe). A shoe should be con-

reserving the term "flat foot" for cases where the arch has really dropped

2 The predisposing causes are Occupation requiring continuous standing, excessive weight, diminution in muscular and ligamentous support, and generally lowered resistance

3 The most common predisposing cause is improper shoes

4 Direct causes Change of occupation, over-use of the feet in standing and walking, and general weakness following an illness

5 The height of the arch is no criterion of the symptoms complained of A high arch may give more trouble than a low arch

6 The disability and deformity of the weak feet may be only temporary and caused by a disproportion between the strength of the feet and the weight and strain to which it is subjected

7 The symptoms of foot strain are (1)

Indisposition to use the feet as much as formerly (2) Tiring quickly when walking (3) Feeling of stiffness while attempting to walk after a rest (4) Pain when walking or after standing for awhile, later on continuous pain (5) Deformed feet (frequently)

8 People with occupations requiring standing, should be especially careful about the care of the feet, including the choice of the shoe

9 The acute foot strain should be relieved by rest, adhesive plaster strappings and hot applications

10 The flaccid (flexible) flat feet are treated by strappings, exercises, then specially constructed plates intended for temporary use only

11 Rigid flat feet should be first converted into flexible flat feet and then treated as such

12 Arch supports, if necessary, should be carefully made for each case separately, after a careful study of the individual patient

## ACUTE LEUKEMIA AND MONONUCLEOSIS \*

By NELSON G RUSSELL, M.D.,

BUFFALO, N Y

THE problem of acute leukemia and one possibly allied condition seems a big one for a short paper of this kind These conditions confront the practitioner very often and one finds from experience that there are too many errors in diagnosis and prognosis to convince him that the problem is anywhere near a solution or the clinical picture as clearly understood as might be

Recent papers by Sprunt and Evans, Blaedon and Haughton, and many others, have indirectly revived interest in the diagnosis of acute leukemia, and Longcope's article in the *American Journal of the Medical Sciences*, December, 1922, has covered the ground very thoroughly in regard to infectious mononucleosis

Our interest in this subject is purely the practical one and the following cases are selected in an effort to give what seems to be one of every group in which they naturally fall, according to the simplest classification—acute myelogenous, acute lymphatic and infectious mononucleosis

*Myeloid Type*—The symptoms of the acute myeloid type, as given, are fever, malaise, temperature which resembles typhoid, recurring chills in some, striking anemia and varying degrees of enlargement of spleen Stomatitis, pharyngitis, frequently showing organisms of Vincent's Angina The nodes are swollen in some cases, though in my experience this is very variable The hemorrhage from the gums and

stomatitis may be very severe and is often accompanied by necrosis

The degree of exhaustion is very great and pulse quite rapid The blood picture is quite definite shortly after the onset in most cases, showing an increase in leucocytes with hemoglobin and red cells decreasing evenly The white count is not enormously increased, though the average is about thirty thousand My cases showed from 1,000 to 80,000 The differential count shows a great number of mononuclear cells which are in size between large or small lymphocytes These cells have a large nucleus and take the stain for peroxidase granules Frank myelocytes may be rare This stain which shows granules in myelocytes and premyelocytes if not too young has changed over to the myeloid group some of the cases formerly classified as lymphatic

*Lymphatic Type*—Acute lymphatic leukemia presents similar symptoms The onset is often abrupt, occasional chills, severe prostration, anemia, sore throat, often with Vincent's organisms and difficulty in swallowing Hemorrhages almost invariably occur in some form Enlarged glands are at all degrees from very slight enlargement to those of considerable size, spleen is usually palpable but not very large Liver is often large later

The blood shows marked anemia with red cells and hemoglobin dropping at the same rate The white cells are much increased, with a normal or diminished absolute number of poly-

\*Read at the Annual Meeting of the Medical Society of the State of New York at Rochester April 24 1924

has also been aggravated by the variety of ill-fitting plates sold at the shoe stores

To answer these objections, I can say that I feel no more hesitation in putting a proper plate on a lame foot which requires rest than I do about putting a sling on a lame shoulder. In both instances they serve the purpose of relieving muscular strain temporarily. But I regard these plates in the same light as a crutch or a cane in the treatment of any joint unable to bear the strain of use. It is, therefore to be discarded when the normal strength has returned and the irritability has disappeared.

It is of course better to use the plate that will cause less atrophy, is easier to fit and holds the foot in the proper position.

When there are enough reasons to suspect improvement, the plate should be gradually discarded. Usually the patient can hope to discard the plates after one or two years. If the foot has been damaged a great deal, they may have to be worn permanently.

### 3 TREATMENT OF RIGID FEET

Rigid flat feet without muscular spasm are often not painful at all. If accompanied by spasm, however, it is quite disabling. They cannot be treated by strapping or a stiff plate. The rigidity and muscular spasm must first be relieved in order to correct the foot. Anesthesia is quite frequently required to attain this. The foot is overcorrected and put in an extremely inverted position and then placed in a plaster cast extending to the knee. The plaster is left on for six to eight weeks, then a foot plate (arch support) can be used. In severe cases of long standing, operative measures to correct the rigid flat feet must frequently be employed. The tendo-achillis may have to be cut if it is markedly contracted. In cases of peroneal spasm an open operation to remove about three-quarters of an inch must be resorted to.

## III STRENGTHENING THE MUSCLES

### (EXERCISES)

The following exercises will suffice for all except special cases.

1 Stand with the feet parallel and rise on the outer borders without twisting the legs or bending the knees. (In this exercise the movement takes place entirely below the astragalus, it calls the adductors of the foot only into play.)

2 With the feet parallel, rise on the outer borders and walk in this position. (This has the same action as Exercise 1, provided the legs are not twisted outward, if one toes in or twists the legs outward, the rotators of the hip are called into play.)

3 Sitting on a chair, with the feet crossed, and resting on the outer edge alternately partially rise and sit.

4 Standing with one foot in front of the other, the front foot turned in and the rear foot resting behind the front leg on its outer edge, lower yourself a number of times by bending the knee, without changing the position of the feet.

5 Standing with the toes closely touching and heels apart, bend your knees as far as possible, without raising the heels from the floor, and then spread the knees, keeping the soles of the feet flat. This exercise is especially useful in cases where the tendo-achillis is contracted.

6 Using several sizes of marbles, pick them up from the floor with your toes and place them in a small basin. At first only small marbles can thus be seized, but gradually larger sizes may be used. The number of marbles picked up will also be increased during the practice. (This exercise is to be used where the anterior arch is depressed.)

### METATARSALGIA

This name has been given to an affection marked by attacks of pain, sharp or burning in character, often of paroxysmal occurrence, and which are usually located in the fourth metatarsophalangeal joint, and occasionally in the second or third. This condition is generally attributed to flattening of the transverse arch of the foot through which the heads of the metatarsal bones fall into abnormal relations to one another, when pressed together by the shoe, mechanical irritation results.

*Treatments*—For temporary relief, and especially when pain is acute, resort may be had with advantage to felt pads applied transversely just back of the metatarsal heads retained by adhesive plaster. Later on, we prescribe a flat foot plate with a prolongation for the anterior arch.

### SHOES

In all cases it is necessary to provide a proper shoe, as the wearing of improper shoes has been shown to be responsible for so many cases of acute foot strain.

The requirements of a proper shoe are

1 It must have sufficient space for the independent movements of the toes, hence it must have plenty of room at the front part of the toes.

2 The heel should be broad and low.

3 The shape of the sole should correspond to the shape of the foot, hence there should be a right and left shoe and the inner border should be straight to follow the line of the big toe.

4 In mild cases of foot strain especially in the case of children, the inner border of the sole and heel of the shoe should be one quarter of an inch higher in order to throw the weight to the outer side of the foot.

### SUMMARY

1 The term "foot strain" should be used as the general term in cases of static foot disability,

reserving the term "flat foot" for cases where the arch has really dropped

2 The predisposing causes are Occupation requiring continuous standing, excessive weight, diminution in muscular and ligamentous support, and generally lowered resistance

3 The most common predisposing cause is improper shoes

4 Direct causes Change of occupation, overuse of the feet in standing and walking, and general weakness following an illness

5 The height of the arch is no criterion of the symptoms complained of A high arch may give more trouble than a low arch

6 The disability and deformity of the weak feet may be only temporary and caused by a disproportion between the strength of the feet and the weight and strain to which it is subjected

7 The symptoms of foot strain are (1)

Indisposition to use the feet as much as formerly (2) Tiring quickly when walking (3) Feeling of stiffness while attempting to walk after a rest (4) Pain when walking or after standing for awhile, later on continuous pain (5) Deformed feet (frequently)

8 People with occupations requiring standing, should be especially careful about the care of the feet, including the choice of the shoe

9 The acute foot strain should be relieved by rest, adhesive plaster strappings and hot applications

10 The flaccid (flexible) flat feet are treated by strappings, exercises, then specially constructed plates intended for temporary use only

11 Rigid flat feet should be first converted into flexible flat feet and then treated as such

12 Arch supports, if necessary, should be carefully made for each case separately, after a careful study of the individual patient

## ACUTE LEUKEMIA AND MONONUCLEOSIS \*

By NELSON G RUSSELL, M.D.,

BUFFALO, N Y

THE problem of acute leukemia and one possibly allied condition seems a big one for a short paper of this kind These conditions confront the practitioner very often and one finds from experience that there are too many errors in diagnosis and prognosis to convince him that the problem is anywhere near a solution or the clinical picture as clearly understood as might be

Recent papers by Sprunt and Evans, Blaedon and Haughton, and many others, have indirectly revived interest in the diagnosis of acute leukemia, and Longcope's article in the *American Journal of the Medical Sciences*, December, 1922, has covered the ground very thoroughly in regard to infectious mononucleosis

Our interest in this subject is purely the practical one and the following cases are selected in an effort to give what seems to be one of every group in which they naturally fall, according to the simplest classification—acute myelogenous, acute lymphatic and infectious mononucleosis

*Myeloid Type*—The symptoms of the acute myeloid type, as given, are fever, malaise, temperature which resembles typhoid, recurring chills in some, striking anemia and varying degrees of enlargement of spleen Stomatitis, pharyngitis, frequently showing organisms of Vincent's Angina The nodes are swollen in some cases, though in my experience this is very variable The hemorrhage from the gums and

stomatitis may be very severe and is often accompanied by necrosis

The degree of exhaustion is very great and pulse quite rapid The blood picture is quite definite shortly after the onset in most cases, showing an increase in leucocytes with hemoglobin and red cells decreasing evenly The white count is not enormously increased, though the average is about thirty thousand My cases showed from 1,000 to 80,000 The differential count shows a great number of mononuclear cells which are in size between large or small lymphocytes These cells have a large nucleus and take the stain for peroxidase granules Frank myelocytes may be rare This stain which shows granules in myelocytes and premyelocytes if not too young has changed over to the myeloid group some of the cases formerly classified as lymphatic.

*Lymphatic Type*—Acute lymphatic leukemia presents similar symptoms The onset is often abrupt, occasional chills, severe prostration, anemia, sore throat, often with Vincent's organisms and difficulty in swallowing Hemorrhages almost invariably occur in some form Enlarged glands are at all degrees from very slight enlargement to those of considerable size, spleen is usually palpable but not very large Liver is often large later

The blood shows marked anemia with red cells and hemoglobin dropping at the same rate The white cells are much increased, with a normal or diminished absolute number of polynu-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester, April 24 1924

clear cells. The lymphocytes predominate, amounting to 90 to 98 per cent of the total.

The few cases I have seen of this disease showed most of the lymphocytes were true to form and did not show the great relative increase of the large cells given in the textbooks as indicating the acute lymphatic type.

*Acute Mononucleosis*—The symptoms of acute mononucleosis are as follows, quoting from the article of Dr. Warfield T. Longcope, published in the *American Journal of the Medical Sciences*, December, 1922:

"The onset is rather gradual, with malaise, headache and irregular fever, occasionally accompanied by chills. In many instances at the onset there is a pharyngitis, an actual tonsillitis, a tracheitis or a cough. Sometimes the lymphoid tissue of the pharynx becomes much swollen. Very frequently the patients complain of sweating. In a few instances there has been abdominal pain with nausea and vomiting. Rarely the first sign of the disease noticed by the patient has been an enlargement of the cervical lymph nodes. More frequently the cervical lymph nodes became enlarged and tender during the first week of the disease. They may reach 1 or 2 cm. in diameter and are quite firm. In some instances the enlargement is confined to the cervical nodes but frequently the axillary, inguinal, even the epitrochlear and possibly the bronchial, lymph nodes are involved and become swollen, firm and tender. In some cases during the first or second weeks the spleen is enlarged, becomes readily palpable and is tender. By the seventh day the mononucleosis is well marked and from this time until the tenth to the eighteenth day the leukocytes increase in numbers and the mononucleosis advances. The fever, which is often mild and rarely goes above 102 or 103, continues irregularly until the tenth to the twentieth day and then gradually subsides. With the fall in temperature the symptoms subside, the lymph nodes recede, the spleen diminishes in size, the leukocytes fall and the mononucleosis gradually disappears. Convalescence is rapid and uneventful.

The prognosis is unfortunately the only thing which can be given the patient, hence an effort should be made to establish a correct diagnosis.

The leukemias have a very clear group of symptoms which suggest a very severe infection, though the cause is still unknown, while acute mononucleosis has similar symptoms without the hemorrhage, marked anemia, or severe prostration.

The diagnosis by the blood smear is extremely difficult to establish without following the case and distinguishing the bone marrow cells by use of the oxadase stain. As many of the abnormal lymphocytes resemble young myelocytes to any but an experienced observer, it is difficult to dis-

tinguish an acute myelogenous leukemia from a mononucleosis.

The differential diagnosis is clear to a certain extent, though in our experience tuberculosis, typhoid fever symptoms and malignant endocarditis have been clung to for a considerable time.

The blood picture of a leukemia is not at all definite, though I have not seen one that did not show a disturbed relation or occasional abnormal leucocyte when searched for. Longcope suggests that glandular fever may be the manifestation of the condition called mononucleosis. Since reading this I have seen four cases which seemed to fit under that heading, but found normal blood reactions in all—just a slight leucocytosis.

#### CASE REPORTS

Miss F. N., age 39—History of scarlet fever, and diphtheria when a child. Has had trouble with throat, hoarseness particularly. Some abdominal distress. Diagnosis of gall stones and chronic appendicitis. There was some evidence of tubercular infiltration, upper right. In 1920, appendix was removed.

During the following year had one attack of gall stone colic. Hoarseness at times. In September tonsils were removed. After ten days a membrane appeared on throat which showed organism of Vincent's angina. In about one week complaint of pain on left side upper abdomen with large spleen extending to two inches below free margin of ribs. This gradually enlarged almost to the crest. Temperature gradually rose to 100 and remained between 102 and 104, with pulse gradually increasing from 110. There were some hemorrhagic spots. Blood culture was negative.

Blood on October 11, was: Hb 60, white cells 5,000, red cells 3,160,000, polys 51 per cent, monos 31 per cent, L monos 9 per cent, trans 5 per cent, eosino 4 per cent. Reds irregular in size, polychromatophilia, one normoblast in 100, several cells resembling Turk irritation forms.

On October 26: Hb 50, whites 6,000, polys 29 per cent, monos 26 per cent, L monos 14 per cent, trans 28 per cent, Baso 3 per cent, reds irregular in size, fewer polychromatophilic cells, no blasts, one resembling Turk irritation.

The patient died six weeks from tonsillectomy and about four and one-half weeks from the beginning of fever and membrane on throat.

The pathologists' report showed: *Spleen*—General and considerable atrophy of the follicles, and myeloid metaplasia of the pulp elements, the latter consisting of numerous partially and completely differentiated myelocytes, and a considerable number of mostly typical megakaryocytes. No nucleated red blood corpuscles. It seems that the enlargement of the spleen is due chiefly to the increase in the pulp as a result of the presence of these myelogenous elements.

*Liver*—Diffuse intracapillary and subendothelial infiltration with myelogenous elements, as in the splenic pulp, but with only very few bone marrow giant cells, and here and there similar infiltration in the interalveolar connective tissue, the whole picture constituted a characteristic picture of myelogenous leukemia, especially as distinguished from the lymphatic variety

This is a case which might easily escape detection on blood examination alone, though the abnormal cells suggested the possibility of leukemia, the second differential count being more suggestive

G B, age 26, clerk—Entered hospital April 14, 1924. Complaint—Rash on body, headache, frontal throbbing in character, weakness, poor appetite, bleeding gums. Onset For previous ten days patient felt sore and tired. Six days before coming to hospital she became sick and vomited and had a bad headache, was in bed next two days, worked on the 11th, but went home in afternoon

On admission to hospital positive findings were history of weakness for eleven days, bleeding gums, purpura eruption bright to dark red, on extremities, neck and upper chest

*Physical Examination*—Bleeding gums, purpura spots, spleen enlarged two fingers breadth below margin. Blood pressure 72/122. Hb 50, leukocytes 25,600, polys 3 per cent, s lymph 4 per cent, Ll 93 per cent. Cells were nearly all large and medium lymphocytes. Oxidase reaction negative. Platelets very scarce. Blood chemistry: Uric acid, 6.6, urea nitrogen, 16.8, creatinin 17, sugar, 106. Coagulation time, 20 minutes. Bleeding time, 20 minutes. Fragility test: Complete, 30 per cent, partial, 37 per cent. The patient grew rapidly worse and on the 18th, vomited a large amount of blood, fluid and clots. She died on the 19th—two weeks after first symptom

Positive autopsy findings were hemorrhagic areas on skin all over body. Blood in gums, in uterus, peritoneum, stomach bowel, pericardium and ovaries

Bronchial and periaortic lymph nodes slightly enlarged and appeared pyoid on section. Spleen

three times normal size, pale, capsule wrinkled, pulp confluent. Bone marrow red and pyoid in appearance

M R, schoolboy, age 15—Gave a history of whooping cough, measles, chickenpox, tonsillectomy at 7, frequent attacks of nausea, tenderness in appendix region

On October 24, 1922, complained of sore throat, weakness and slightly enlarged glands in neck. Temperature slightly elevated. Culture showed staphylococcus and streptococci. Smear showed some Vincent's organisms

During this time the boy ran a temperature of 99 to 103, gradually returning to normal in about three weeks. There was considerable depression and some general aching. The nodes in the neck, axilla and groin were enlarged, some in neck to size of small walnut, one month later these were normal. The spleen was palpable for a few days, a blood count about a year before showed a normal differential. The treatment in the case was small doses of neo-salvarsan every second day for four doses

These cases were selected because they may serve to illustrate some of the difficulties which the practitioner encounters

The first one shows a picture of an infection occurring, the convalescence from a simple tonsillectomy and which never gave a count above six thousand white cells and only twice showed pathological cells in very small numbers. The symptoms, fever, anemia, sore throat and hemorrhage, taken as a whole, gave a good picture of leukemia, but the blood count did not confirm this though fairly frequent counts were made. It had been more persistent in our search of the slides, possibly more pathological cells might have been found. The pathologist, Dr. Roman, made an unqualified diagnosis of acute myelogenous leukemia

The second was a clean cut case of acute lymphatic leukemia running its entire course in fifteen days. There was little if anything lacking to complete the clinical picture. The blood specimens were classical, showing a great increase in lymphocytes. Many of the pathological forms were present, but none showed oxidase granules

† Abnormal cells during October 1922. Some pathological mononuclears.

The post-mortem findings, however, showed marked changes in the bone marrow and relatively slight changes in the general lymphatic system. Fortunately the treatment has so little effect that its discrepancy between the clinical and pathological findings makes little difference.

The third case seems to me a fair sample of acute infectious mononucleosis, which appears perfectly simple, though the diagnosis was not made until the course was very apparent.

The symptomatology of the acute leukemia and acute mononucleosis seems almost identical to a certain point when the more severe signs, as hemorrhages and grave anemia, appear. These seem to be two distinct groups. One going to a

fatal termination, and the other, in nearly all cases, to complete recovery with a normal blood response to ordinary infections.

Nothing can be said about treatment of acute leukemia for the usual procedures have failed to give any relief, and in a few cases we have thought that the disease progressed more rapidly after X-ray and radium treatment. Transfusion has also been used without effect.

Acute mononucleosis seems to run a self limited course. Our few cases recovered while taking arsenic in some form. This was used partly from habit and partly because the Vincent's organisms were present and these apparently yield to arsenic.

## SERUM THERAPY OF PNEUMONIA IN NEW YORK STATE \*

By AUGUSTUS WADSWORTH, M D,

ALBANY N Y

I APPRECIATE greatly this opportunity of presenting to you the work that has been done in New York State in the development of the serum therapy of pneumonia, together with the results that have been obtained in the treatment of cases. The work was started in 1915 when centers for the determination of type and the distribution or administration of anti-pneumococcus type I serum were established to serve as large a proportion of the population as it was possible to reach in such a large state. Since then, the distribution and use of the serum has become more general and is now no longer limited to these centers, as many of the local laboratories are equipped and qualified for the work. From the beginning, the serum, tested by the methods and according to the standards still in force, has been of the highest potency.

The published reports of eighteen groups of cases of type I pneumonia treated with anti-pneumococcus serum—eleven from Army camps and seven from civil hospitals—have been reviewed in another paper. The reduction in mortality is not convincing of the value of serum treatment, but it is only necessary here to note essential facts in order to understand how impossible it is to arrive at any definite conclusion, either favorable or unfavorable in that respect. A number of conditions affect the significance of statistical reports—the great variation in the mortality of pneumonia, the almost insuperable difficulty of securing satisfactory control series or untreated cases for comparison, uncertainty with regard to the potency of some of the early serums before standardization was instituted by the federal authorities—and more than anything else especially in the civil population, the selec-

tion of serious cases for treatment, or delay in treatment until the prognosis becomes obviously unfavorable. In addition, there are fundamental conditions underlying the development and course of pneumonic infection of the lung which determine to a large extent the limitations of serum therapy in pneumonia.

Reports from the Rockefeller Institute Hospital, where conditions for serum treatment and the results obtained from it are more favorable than elsewhere, give a total of 195 serum-treated cases, with 18 deaths, a mortality of 9.2 per cent. In this hospital there is no question of the selection of cases, delay in treatment or of the potency of the serum used.

As previous reports, with the exception of the one from the Rockefeller Hospital, did not give definite information in this regard, we decided to go over carefully the cases in New York State which were all treated with serum of known high potency, produced by uniform methods in our laboratory. The records of these cases illustrate strikingly the importance of securing complete and reliable data if correct inferences are to be drawn from statistical reports.

A miscellaneous group of 151 cases is compiled from records kept in the central laboratory at Albany of scattered cases occurring throughout New York State, and reported by local physicians.

Although complete data on all the thirty-three fatal cases which were treated with the serum are not available, sufficient information is recorded in many of them to indicate the extent to which delayed or inadequate treatment affected the statistics of this group. These factors are so evident that the control series of 218 untreated cases with a mortality of 18.81 per cent, approxi-

\*Read at the Annual Meeting of the Medical Society of the State of New York at New York City May 23, 1925.

mately the average mortality in pneumonia, cannot be considered a representative series for comparison. The mortality of the more serious cases of pneumonia may reach 40 or 50 per cent. But this general fact cannot be regarded as constituting a satisfactory basis of comparison. More striking possibly to those who have had an opportunity of observing the effect of treatment at the bedside, is the marked improvement in the cases, often with sharp amelioration of the symptoms and the febrile reaction, following the administration of the serum. These signs, however, cannot be distinguished from those evident in the spontaneous recovery by crisis. Thus, even with complete data it is impossible to secure convincing evidence of the beneficial action of the serum.

Undoubtedly better conditions of treatment prevailed in the series of cases treated in one district, the City of Rochester. Dr. Joseph Roby reports 126 cases treated with serum, which had a mortality of 13.6 per cent, as contrasted with 19 per cent of the parallel series of 126 cases in which serum was not given. Nevertheless, the selection of serious infections and delay in treatment were evident in this series and noted especially by Dr. Roby, who administered the serum in many, if not all, the cases.

The reports on cases in the Army camps treated with serums from the same source approach the other extreme. At Fort Bliss, Nichols reports sixty-three type I serum-treated cases, with a mortality of 8 per cent. At Camp Wheeler, there were seventy-two cases with only two deaths, a mortality of 2.8 per cent—yet the mortality in these outbreaks exceeded 20 per cent, whereas the average mortality of pneumonia in the Army, according to the Surgeon General's report, was 10.7 per cent. From various camps, Sutton collected thirty-three cases which were treated with serum and in which no deaths took place. These cases probably constituted the usual incidence of pneumonia in the Army and were not associated with any particular outbreak. Thus, in these three groups, 168 cases were treated, with a mortality of 4.68 per cent.

Reports on the use of this particular serum

of known and uniform potency are seemingly at variance with one another. They possibly represent extremes and can only be attributed to the conditions under which the cases were treated. The fact that young, healthy adults were selected by the draft boards was doubtless an important factor in determining the low mortality in the Army hospitals in both treated and untreated groups of cases, but in the outbreaks of pneumonia in the camps the mortality was equal to or exceeded that ordinarily recorded in civilian hospitals, and it was largely these cases which were treated with serum. It is evident that delay in treatment affects the results of serum therapy to such an extent that it is useless to give the serum late in the course of the very serious infections.

The study of the fatal cases, however, demonstrated the limitations of serum therapy. On this account, I wish to emphasize the importance of complete records and reports on the use of the serum which is distributed to the physicians of the state by the laboratory. Apart from the accidents of anaphylaxis due to faulty methods of administration there is no evidence that the serum is harmful. This fact, however, does not justify excessive dosage or treatment prolonged beyond reason. The serum should be given slowly to determine the tolerance of the individual after careful desensitization. The dose should be at least fifty cubic centimeters, preferably one hundred. It should be repeated at eight or twelve-hour intervals. Four or five doses suffice in nearly all cases. The exceptionally prolonged or the complicated cases require special study to determine the wisdom of continuing the treatment.

In conclusion, I may state that although it is impossible to foretell the results of serum therapy in individual cases, and although there are cases in which the serum will not bring about recovery, it is evident that anti-pneumococcus type I serum of known high potency, if administered promptly in adequate dosage by physicians experienced in giving serum treatment, will be shown to be of definite practical value.

The post-mortem findings, however, showed marked changes in the bone marrow and relatively slight changes in the general lymphatic system. Fortunately the treatment has so little effect that its discrepancy between the clinical and pathological findings makes little difference.

The third case seems to me a fair sample of acute infectious mononucleosis, which appears perfectly simple, though the diagnosis was not made until the course was very apparent.

The symptomatology of the acute leukemia and acute mononucleosis seems almost identical to a certain point when the more severe signs, as hemorrhages and grave anemia, appear. These seem to be two distinct groups. One going to a

## STANDARDS OF THE PRACTICE OF MEDICINE

When a physician publishes a plea for higher standards of medical practice, chiropractors and other cultists are likely to quote the medical author to prove that physicians generally are an incompetent lot and do not know their business. Since nearly every patient that goes to a cultist has been treated by physicians without relief, the published confessions of the physicians tend to confirm the evidence of experience that doctors do not always cure the conditions for which they are consulted. The obvious conclusion is—since the doctors fail, let some one else try.

It is not such a bad thing for the medical profession that quacks and cultists are watching the doctors' failures and are advertising them to a

public that is always ready to accept any new healing theory as the latest and best scientific discovery in therapy. The quack gives the impression that his diagnosis is absolutely correct and that his prescription is surely efficacious—if the patient is not satisfied, the fee will be cheerfully refunded. Can a conscientious physician arouse this degree of confidence in his patients? There is no doubt that some do.

What is the element which enables some physicians to hold the confidence of their patients? Think over the names of your personal friends who are highly successful general practitioners of medicine. What do they do that is different from the methods of their confreres? For one

thing, they examine their cases, and substitute certainty for guess work.

As a corollary to their examination, these successful physicians keep exact records of their patients—physical examination, diagnosis, treatment and follow-up observations. This still further promotes certainty on the part of the physician and confidence on the part of the patient, and if that patient wanders from the fold of the physician on the solicitation of a testimonial writing friend, he will come back some evening to the office where his exact physical state is recorded in writing rather than on the uncertain pages of memory. A patient thinks that his memory is as good as the doctor's, but he is convinced by a written record of his case. The most successful physicians make a complete physical examination of every new case.

Dr Frank Billings of Chicago has something to say in this line in the January issue of the *American Medical Association Bulletin*. He says

"I made a point never to take more than four new patients in any one day in my office. I saw some patients daily who had been to me before, but I wanted plenty of time to go thoroughly over new patients. I had always been struck by the fact that patients who stripped sometimes did it reluctantly and often made a remark that they had never been unclothed for examination before. So for two years I gave my secretary every night the number of new patients who had never been disrobed for examination before. During those two years there were approximately 500 patients, the members of doctors' families. Over 75 per cent of the total patients, members of doctors' families included, had never had their clothes off in an examination, and every one had suffered from a chronic disease."

Dr Billings sets a standard which is both ideal and practical. Not every physician can choose his cases and score one hundred per cent in making the examinations of his patients, but not all the work of a doctor consists of emergency, long distance calls, and in the course of five years a doctor could secure records of the examinations of practically every individual in the families whom he calls his patients. Think what this will mean in the practice of any doctor who maintains this standard of the practice of his profession.

Are physicians practising medicine according to the highest modern standards? No. Not all physicians have the time to give every new patient a complete physical examination. If the majority of physicians subjected every patient to all the examinations and laboratory tests that are available to the average practitioner, there would not be doctors enough to visit half of the existing cases of sickness, and the quacks would get hordes of patients who would like to employ competent physicians. It requires judgment to know when to insist on a general examination.

Are doctors treating all those who are really sick and would not get well without expert medical assistance? If they are, then physicians need not be envious of the success of quacks. Physicians reach a fairly high score in the diagnosis and treatment of acute conditions, but many doctors are not deeply interested in chronic cases and do not seem to care if they score a low mark in their diagnosis and treatment.

How much responsibility for the prosperity of quacks rests upon general practitioners who lack pride in diagnosing and treating chronic cases according to the highest medical standards?

F O

---

## HOW TO MAKE A PERIODIC HEALTH EXAMINATION

We sometimes receive letters asking how to make a periodic health examination. We might just as well be asked how to practice medicine. The one feature wherein a periodic health examination differs from the examination of a patient who is evidently sick is that the periodic examination deals with a patient who is presumably healthy, or at least his disability is of a mild degree. Hence there has arisen the term *pre-clinical* conditions, meaning those conditions which are not evident without a careful correlation of both the examination and the history.

Modern refinements of diagnosis enable a physician to read the human barometer for the signs of an approaching storm, and to prepare the patient for its onset, and even to steer the patient completely away from its path. The practice of pre-clinical medicine consists in the diagnosis and treatment of lowered states of health and of slight degrees of deviation from health. The field is as broad as that of medicine itself. It embraces

obstetrics, and surgery, dentistry and dietetics, and so on down the whole list of medicine and its allied sciences.

How shall anyone prepare himself to practice in all this broad field? If he is a general practitioner, he is already expected to be able to recognize a deviation from the normal in every line of examination. If he cannot explain a condition himself, he will call in a consultant who can explain it. He will consider every apparent abnormal symptom and sign, and will give his best effort to its interpretation. He will not be a pessimistic prognosticator and tell every patient that he is threatened with heart disease or Bright's, neither will he say to the patient "Run along and forget it." He will consider every point in its relation to the rest of the patient's body, and will do some honest thinking and possibly research in regard to it. This is what constitutes the practice of pre-clinical medicine.

## LEGISLATURE OF 1925

By the time this Journal reaches the members of the Medical Society of the State of New York it is very probable that the Legislature of 1925 will have passed into history. And it can be said that in many respects it has been a peculiar situation. This is so because of the fact that the Legislature has been of one political faith and the Governor of opposite faith. Therein many phases of legislation may be said to have suffered through lack of interest on the part of the legislators in arguing what might become of features presented to the State Executive in view of this division in political allegiance.

In general, the Medical Society may be said to have been treated with the greatest courtesy by the legislators during this past year. Your Committee on Legislation has received far greater courtesy through its representatives and emissaries who have appeared before the various committees in the legislature, and the questions under discussion have received from the legislators a more free expression of reason in sound thinking than in several of the years past.

It is to be expected that with the desire on the part of reasonable people to learn more of the true aims of science and medicine in the prevention, treatment, and care of bodily ailments, it has been a pleasure on the part of the medical profession and its representatives to furnish such knowledge and answers to questions as were readily at hand.

The majority of the legislators, even some of those who are opposed to the medical profession because of a belief in the existence of a so-called medical trust, have shown the utmost courtesy in discussing and arguing the thoughts advanced by members of the profession.

There have been some, however, as is found in all groups, who through lack of desire, of education or of reasoning power or other reasons, have refused even to grant to the profession a meed of praise in its endeavor to alleviate human ills.

For such is the course of the political life of this nation.

Your profession has not asked for things unreasonable during this past year, but through its ramifications in the County Societies and the governing body of the State Society, it has endeavored to maintain calm and mature judgment that it might steer a clear course in questions pertaining to the public health.

It has opposed with vigor questions of legislation inimical even in thought to the welfare of the people who are to follow this generation. Most of this opposition has been advanced by reason of experiences gained in public health matters in other States and countries where these same questions have been tried out and have been found inadequate of practical application, or

absolutely at variance with the advances of the other sciences which go hand in hand in this life.

That the question of public health is one of vital importance can be gainsaid by no one.

The Chief Executive of this State, in his message to the Legislature on January 7th, 1925, devoted no less than over 10 per cent to public health topics, mentioning in detail the various efforts on the part of governmental branches of the State to promote public health and safeguard the citizens in this respect.

Some of his suggestions have already been put into law.

Unfortunately some have been so drafted as to bring criticism from medical and other sources, but in the main only because of the practical application as would be put in force rather than in the theory advanced, but to the credit of the Governor may it be said, that his thoughts and action have seemed consistently to bear out a set policy on his part to benefit the whole State in its needs regarding public health, while leaving the details to those who should know and who are looked upon as being most competent to advise.

No longer is the question of public health to be relegated to a secondary position but rather through the co-ordinate efforts of the State government and the various members of the profession of medicine it has been raised to a position of paramount importance in this State and from this position of the State of New York are other states now fashioning their public health measures.

It is to be hoped, but it would seem almost a miracle, that all of the measures in which the Medical Society of the State of New York has been interested in the affirmative, might be enacted into law, while those matters in which frank opposition has been voiced might be defeated, and yet greater interest has been shown on the part of the group of physicians as a whole and through the awakening of more individual physicians as to their duties than has been exhibited in past years.

Your Committee on Legislation has endeavored to fulfill its functions as interpreted by its members, and through the guidance by vote and opinion of the individual County Societies to forward or retard the various types of legislation. This has been no easy matter, and from year to year becomes harder by reason of more compact opposition on the part of individual groups wishing to forward their special types of legislation, and strange to say, by reason of these same lay groups, in the majority of instances, giving but half hearted support to such type of legislation as the Medical Society desires to see forwarded.

Credit without stint should be given on the part of the members of the profession to the

reawakening in the various County Society organizations, brought about undoubtedly through renewed interest in medical subjects, in civics and in politics, engendered by visits from your State officers and your Executive Officer and the weekly publication of the State Journal under the guidance of its Editor-in-Chief and his associates

The Presidents of the District Branches have improved the opportunities now and again offered through the Journal, undoubtedly to the betterment of legislative effort, but there still is vast room for advancement and improvement

Attention is called to this, the next to the last issue in which the columns on legislation will fill the larger part of the Journal. Your Committee on Legislation of the Medical Society must now turn its effort toward a report to be rendered to the House of Delegates and to give an account of its stewardship to the governing body of the Society. That its efforts may be along the lines of advance in suggestions and recommendations it asks from individual members of the Society,

communications, the thoughts of which may be embodied in its report to the House of Delegates, and suggestions, resolutions or recommendations from the county society groups which make up the State Society as a whole

It has tried to be fair in all of its actions to accord its views to the wishes of the majority of those who have been consulted on legislative matters. Physically it could not reach out and obtain the view of each individual member, but opportunity now is given for expression of thought on the part of any individual member who may have disagreed with the attitude of your Committee and who may not be in a position to project his thought into the governing body of the Society—the House of Delegates

In closing this, the last real editorial work of your Committee, it wishes to thank those who have endeavored to work with it, even though they may have advanced opinions opposite in principle to those brought forward by the Committee

## THE NURSING SITUATION

One of the problems before the physicians of New York State is that of nursing. Physicians generally will agree that the following facts exist

1 The number of nurses is not equal to the demand for their services

2 There are many specialties in nursing—operating room, obstetrical, psychiatric, public health, contagious disease, tuberculosis, and so on for a long list of specialties

3 A skilled nurse who understands the post-operative care of cases of major surgery is the product of long training, and three years is none too long to develop that type of nurse

4 The nurse who is highly trained deserves special recognition with the title, "registered nurse," and the privileges and social standing which go with that title

5 The demand for highly trained nurses exceeds the supply

6 In nursing, as in any other line of work, an under supply of workers leads to undue independence both in accepting cases and in continuing with them under unpleasant conditions

7 The average highly trained nurse is a specialist who confines her activities to certain hours, and certain duties

8 Many persons object to having a trained nurse in their homes because of the necessity of having to have "some one to wait on the nurse"

9 There is a very great field for the services of nurses who are less highly trained,

and who are willing to do some kinds of house-keeping in addition to the care of the sick

10 There is a grave danger that unskilled nurses, like incompetent healers, may pretend to a knowledge which they do not possess, and may endanger the health or life of the patient and the reputation of the attending physician or surgeon

11 There are great difficulties in the way of establishing several degrees of fitness for nursing and of credentials of capabilities

12 The board for licensing nurses in New York State is constantly raising the standards for graduating nurses, and are continually adding training in the specialties such as psychiatry

13 Nurses in training are expected to study many branches which are preliminary studies in medical courses, and as a result of time spent on theoretical subjects, insufficient time is spent in practical bedside nursing

14 Is it not possible to give candidates a training of two years in the fundamentals of nursing, and graduate them with reliable credentials which indicate their fitness to care for common cases in either a private house or a hospital?

15 Who can consider these conditions and advise a remedy, better than the leaders of the Medical Society of the State of New York?

The State Society has a committee that is actively working on the subject, and a constructive plan of action may be expected to result from their labors

By GEORGE W. WHITESIDE, Esq.  
Counsel Medical Society of the State of New York

## FRACTURES OF BOTH FEMURS, DELAYED UNION, GANGRENE OF LEFT FOOT AND LEG WITH AMPUTATION

A man about 54 years of age, while crossing a public highway, was struck and run over by a taxicab, sustaining fractures of both of the femurs and numerous abrasions and contusions on both legs from the hips to the feet. He was removed to a hospital where the contusions were given first aid treatment and the fractured limbs placed in splints. The family physician, a general practitioner, was called to attend the man. He in turn called in a surgeon who had the patient removed to another hospital on the following day. Upon admission at that hospital there was found an abrasion of about an inch in diameter on the forehead, the patient was very nervous and his lips pale. There were abrasions on both hands on the left knee joint and over both legs and feet. The fracture of the right femur was at about the middle third and a sharp bony edge projected immediately under the skin. There was a definite false point of motion at this point, crepitus being elicited. The patient was unable to flex the right thigh. The left femur was fractured at about the middle third and in a transverse line, there being marked tenderness, and a false point of motion was present in the left leg. There was eversion of both feet. The upper fragments of the fractured bones were markedly displaced forward and outward and the lower fragments backward and inward. Under a general anaesthesia and using a Hawley table, reduction was made of both fractures, the surgeon procuring good alignment and end apposition being obtained. A plaster cast extending from the chest to and including both legs was then applied. The patient was returned to bed in fair condition.

On the following day X-rays were taken which showed a transverse fracture of the left femoral shaft four inches below the articular surface. The anterior posterior view showed good alignment, the lateral view showing a posterior displacement of the lower fragment. An X-ray of the right leg showed a transverse fracture of the femoral shaft. The lateral view showed a marked displacement with angulation, the anterior posterior view showing slight angulation. At the time of the taking of the pictures the patient was suffering from shock and was in severe pain. His pulse was weak, it being necessary to stimulate him. It was until April 11 that he waited four days, removed the

casts from both legs and applied Hodgens splints suspended on a Balkan frame. Traction was applied to both legs with counterweights and the knees bent. The patient was maintained in this apparatus until May 2, daily adjustments of the apparatus being made as was indicated by the patient's condition for the necessity for such adjustments. X-rays taken between April 11 and May 2 of the right leg showed angulation with slight over-riding. X-rays of the left leg likewise showed over-riding and slight angulation. During this time the patient was given the continuous personal care and attention of the surgeon, and the necessity of the performance of an open operation was discussed with the patient's family.

A physician specializing in bone surgery was called in consultation who approved of the treatment that was then being rendered to the patient, and advised the performance of an open operation upon the right leg. On May 2nd, under a general anaesthesia, using a Hawley table, an open operation was performed upon the right leg and a four-screw Lane plate inserted. Before the insertion of the Lane plate the various other methods of holding the fractured bones in apposition were considered, but due to the condition at the point of fracture and the patient's physical condition, the use of Lane plates was deemed the best and most advisable procedure to follow at that time. At the open operation a bone to bone apposition was obtained on the internal side, there being a hiatus on the external side. Upon completion of the operation a cast was applied to both legs, extending above the umbilicus. The cast on the left leg, however, did not reach the ankle, as there was an open wound on the lower left leg. At the time of the performance of the open operation upon the right leg, because of the patient's physical condition, it was not possible to operate upon the left leg. After the open operation the patient was returned to bed in poor condition and it was necessary actively to stimulate him. His pulse was rapid, skin cold and clammy and he complained of severe pain in the lower extremities. Within a few hours after the performance of the operation on the right leg, the left foot became cold and cyanosed and the cast on that leg was immediately removed, the foot elevated and heat applied and baking ordered in an endeavor to stimulate circulation. The patient continued under daily observation

and care of the surgeon and by May 23rd had developed bed sores rendering it necessary to remove the entire cast and there was then applied posterior and lateral splints to the right leg. At that time it was not possible to apply any splints to the left leg because of the gangrenous condition which had developed in the left foot. On May 12, an X-ray was taken of the right leg which showed the Lane plate in position with perfect apposition and no angulation. On May 13, a window was cut in the cast on the right leg over the site of operation. The wound was then found to be clean and was dressed at that time. This wound was dressed daily and on May 17, there was a slight serous discharge from the wound which was open and a large amount of greenish-black fluid with a sour odor was evacuated and a rubber tube inserted for drainage. This wound continued to drain for a long period of time. On May 26, on manipulation a pocket of pus was opened in the wound. From time to time the wound was irrigated with Dakin solution, but it was necessary to discontinue the use of this as the same cause an irritation to the skin. An X-ray taken on June 18 showed the Lane plate had lost its hold and the two upper screws were out of their original position. Two days later the Lane plate and the screws were removed. At various times between May 19 and June 20, it was necessary to remove parts of the cast on different portions of the right leg as the patient developed sores and complained of pain. On June 22, both legs were placed in a wire mesh splint, at that time it being impossible to apply traction as both legs were emaciated, particularly the left one. The gangrenous condition of the left leg progressed between May 4 and July 18 and during this period there was from time to time a sloughing of the tissues, and on July 18 the gangrenous part of

the left foot was amputated. After this amputation the patient remained in the care of this surgeon only until July 26, when he was removed to another hospital and passed into the care of another surgeon. He remained at that hospital from that date until about February 18 of the following year, during which time various methods of treatment and operation were performed upon him to produce union in the fractured femurs. It was also necessary to make a further amputation of the left leg, adhesions had formed in both of the knee joints which had to be broken up.

The operative wound on the right leg eventually healed and union was procured in both of the femurs, and with the aid of an artificial foot the patient was able to be about.

The first surgeon who treated him was paid only part of his bill. He then directed that an action be instituted to collect his unpaid bill. This action was met by a suit on behalf of the patient charging the surgeon with malpractice and alleging that his entire course of treatment, the operation and the use of the Lane plates were carelessly and negligently done and not in accordance with the proper and approved practice, that by reason of such alleged negligence, union was delayed in both of the fractured femurs, gangrene was permitted to develop in the left foot, resulting in amputation, and the patient was confined to a hospital for many months and sustained permanent injuries. The malpractice action came on for trial and after conference with the plaintiff's attorneys we were able to convince them that instead of the plaintiff having any complaint or cause of action against the surgeon, that he should be thankful for all that the surgeon had done to save the patient's life. As a result, the patient consented to the discontinuance of his action against the surgeon.

	Assembly Int 1463—Chiropractic (Bolton)

## BIRTH CONTROL HEARING

The hearing before the Assembly Committee on Codes on Assemblyman Boyle's Bill (A Int 987) which would authorize the use of contraceptive measures by physicians was attended by the leaders of the groups usually represented. The arguments presented were the same as in former years except that the proponents seemed inclined this year to speak more definitely of mechanical methods, which they said could be made 100 per cent perfect when applied by a physician, and that the scheme was applicable to married women only.

Among the proponents were Mrs Margaret Sanger and one or two persons in charge of her clinics.

The opposition was limited to a representative of your Committee on Legislation and the Rev William Sheaf Chase, who said that he represented nobody but himself, but is the President of the New York Civic League.

No action was taken by the Committee after the hearing because the Assembly had already gone into Rules.

Without doubt the bill will remain in committee.

In this connection, however, it might be well to speak of a point brought out by one of the proponents in the discussion, that, at present the

law is not sufficiently elastic to cover all occasions when the physicians may wish to advise contraceptive measures. The law reads that the physician may employ such measures to save life or prevent disease, and as was pointed out, that does not cover a case where it is thought wise that a woman should not bear children because of her tuberculosis, and the Chairman of the Committee on Codes suggested that perhaps in another year the law could be revised to read "to save life, prevent disease or *preserve the patient's welfare*"

The Representative of your Committee on Legislation was nonplussed for a minute in his opposition by a member of the committee exhibiting the result of a ballot taken on the bill by the physicians in a County Society. A majority of the society were recorded in favor of the enactment of the bill. It was concluded, however, that most likely those who voted affirmatively were not favoring the bill as it read but rather as Dr Elting had expressed it in his plea for the measure, "for the right to use measures to prevent conception when in their judgment they thought it was for the benefit of their patients." This controversy demonstrated the misunderstanding that can arise from a hasty or a prejudiced reading of a bill.

## LEGISLATIVE BUREAU

The work of this department will soon close to a very large degree and a perusal of page 26 of the January 16th, 1925, issue of the Journal, will tend to show that an advance has been made along the lines of information during this short period in which the Legislature has been in session.

While much of the legislation at the time of this writing is still pending, it is to be hoped that many of the bills still in committee may be passed which we have deemed as advanced by departmental government bureaus, and that such legislation as is inimical may be defeated.

Your Legislative Bureau has not been helped to the full extent sought in the recommendations,

and yet it is a well known fact that the medical profession moves slowly but surely in its efforts for a higher and higher stand in the protection of public health, and we as members of that profession in the State of New York have attempted to do our part as we saw it during this past session politically.

It is to be hoped that the same high standards will be maintained in the individual communities during the coming year and that when the next Committee on Legislation convenes it may find the ground prepared and the soil ready for more intensive work than has ever before been experienced.

## SUMMARY OF BILLS INTRODUCED IN LEGISLATURE IN SENATE

### Prohibition Enforcement

Senate Int No 29 (conc Assembly Int 527)  
—Assembly bill passed, on order of third reading  
in Senate

*Attitude* Neutral

### The Narcotic Bill

Senate Int No 115 (conc Assembly Int 215)

*Comment* Senate bill on order of third reading,  
Assembly bill still in committee No further  
comment

*Attitude* Favored

### Requiring the Licensing of Private Institutions for the Treatment of Drug Addicts

Senate Int No 116 (conc. Assembly Int 216)

*Comment* Still in committee

*Attitude* Favored

### The State Department of Education Bill Amending the Medical Practice Act

Senate Int No 211 (conc Assembly Int 307)

*Comment* Senate bill still in committee, Assembly  
bill on order of third reading, and will undoubtedly be on the calendar Tuesday or Wednesday,  
March 24th or 25th

*Attitude* Favored by State Society

### Inspection by State Charities Boards of Children's Institutions

Senate Int No 228 (conc Assembly Int 236)

*Comment* Still in committee

*Attitude* Neutral

### Qualifications of Examiners in Lunacy

Senate Int No 263

*Comment* Still in committee

*Attitude* Opposed by State Society

### County Public Health Nurses

Senate Int No 283 (conc Assembly Int 399)

*Comment* Senate bill passed March 16th,  
March 17th to Assembly Public Health Committee

*Attitude* Bill opposed by State Society in its  
original draft After certain amendments it was  
favored

### Health Service in Schools

Senate Int No 302 (conc Assembly Int 748)

*Comment* Senate bill on order of third reading,  
Assembly bill still in committee

*Attitude* Favored by State Society after  
amendments were made

### Vaccine Virus

Senate Int. No 351 (conc Assembly Int 536)

*Comment* Bill passed both houses Now in  
the hands of the Governor

*Attitude* Neutral

### Injured Employee to Select His Physician

Senate Int No 380 (conc Assembly Int 570)

*Comment* Still in committee

*Attitude* Favored by State Society

### The Drugless Practitioner Bill

(By Gibbs)

Senate Int No 473

*Comment* March 18th, amended and recom-  
mitted

*Attitude* Strongly opposed by State Society

### Inspection of School Children

Senate Int No 586 (conc. Assembly Int 580)

*Comment* Passed Senate, now in Assembly  
Public Education Committee

*Attitude* Neutral

### Free Choice of Physician

Senate Int. No 594 (conc. Assembly Int 301)

*Comment* Still in committee

*Attitude* Favored by State Society

### Practical Tests of Injured Persons

Senate Int No 647 (conc Assembly Int 184)

*Comment* Still in committee

*Attitude* Strongly opposed by State Society

### Physically Handicapped Persons

Senate Int No 671 (conc Assembly Int 868)

*Comment* On order third reading in Senate,  
also on third reading in Assembly

*Attitude* Neutral

### Abolishing Office of Coroner—Westchester County

Senate Int No 673

*Comment* Bill passed both Houses and was  
signed by the Governor on March 16th Now  
Chapter 139, Laws of 1925

*Attitude* Neutral

### Admission of Foreign Practitioners

Senate Int No 693 (conc Assembly Int 950)

*Comment* Still in committee

*Attitude* Neutral

### In Relation to Pharmacies

Senate Int No 632 (conc Assembly Int 802)

*Comment* Still in committee

*Attitude* Opposed

### Revocation of License to Practice Medicine

Senate Int No 701

*Comment* Still in committee

*Attitude* Neutral

### Hospital for Crippled Children at West Haverstraw

Senate Int No 786 (conc Assembly Int  
1074)

*Comment* Still in committee.

*Attitude* Neutral, until requested by Confer-  
ence of County Chairmen to urge that no action  
on this bill be taken for another year

### State Institute for Study of Malignant Disease

Senate Int No 787

*Comment* Still in committee

## BIRTH CONTROL HEARING

The hearing before the Assembly Committee on Codes on Assemblyman Boyle's Bill (A Int 987) which would authorize the use of contraceptive measures by physicians was attended by the leaders of the groups usually represented. The arguments presented were the same as in former years except that the proponents seemed inclined this year to speak more definitely of mechanical methods, which they said could be made 100 per cent perfect when applied by a physician, and that the scheme was applicable to married women only.

Among the proponents were Mrs Margaret Sanger and one or two persons in charge of her clinics.

The opposition was limited to a representative of your Committee on Legislation and the Rev William Sheaf Chase, who said that he represented nobody but himself, but is the President of the New York Civic League.

No action was taken by the Committee after the hearing because the Assembly had already gone into Rules.

Without doubt the bill will remain in committee.

In this connection, however, it might be well to speak of a point brought out by one of the proponents in the discussion, that, at present the

law is not sufficiently elastic to cover all occasions when the physicians may wish to advise contraceptive measures. The law reads that the physician may employ such measures to save life or prevent disease, and as was pointed out, that does not cover a case where it is thought wise that a woman should not bear children because of her tuberculosis, and the Chairman of the Committee on Codes suggested that perhaps in another year the law could be revised to read "*to save life, prevent disease or preserve the patient's welfare*".

The Representative of your Committee on Legislation was nonplussed for a minute in his opposition by a member of the committee exhibiting the result of a ballot taken on the bill by the physicians in a County Society. A majority of the society were recorded in favor of the enactment of the bill. It was concluded, however, that most likely those who voted affirmatively were not favoring the bill as it read but rather as Dr Elting had expressed it in his plea for the measure, "for the right to use measures to prevent conception when in their judgment they thought it was for the benefit of their patients." This controversy demonstrated the misunderstanding that can arise from a hasty or a prejudiced reading of a bill.

## LEGISLATIVE BUREAU

The work of this department will soon close to a very large degree and a perusal of page 26 of the January 16th, 1925, issue of the Journal, will tend to show that an advance has been made along the lines of information during this short period in which the Legislature has been in session.

While much of the legislation at the time of this writing is still pending, it is to be hoped that many of the bills still in committee may be passed which we have deemed as advanced by departmental government bureaus, and that such legislation as is inimical may be defeated.

Your Legislative Bureau has not been helped to the full extent sought in the recommendations,

and yet it is a well known fact that the medical profession moves slowly but surely in its efforts for a higher and higher stand in the protection of public health, and we as members of that profession in the State of New York have attempted to do our part as we saw it during this past session politically.

It is to be hoped that the same high standards will be maintained in the individual communities during the coming year and that when the next Committee on Legislation convenes it may find the ground prepared and the soil ready for more intensive work than has ever before been experienced.

## SUMMARY OF BILLS INTRODUCED IN LEGISLATURE IN SENATE

### Prohibition Enforcement

Senate Int No 29 (conc Assembly Int 527)  
—Assembly bill passed, on order of third reading  
in Senate  
*Attitude* Neutral

### The Narcotic Bill

Senate Int No 115 (conc Assembly Int 215)  
*Comment* Senate bill on order of third reading,  
Assembly bill still in committee No further  
comment  
*Attitude* Favored

### Requiring the Licensing of Private Institutions for the Treatment of Drug Addicts

Senate Int No 116 (conc Assembly Int 216)  
*Comment* Still in committee  
*Attitude* Favored

### The State Department of Education Bill Amending the Medical Practice Act

Senate Int No 211 (conc Assembly Int 307)  
*Comment* Senate bill still in committee, As-  
sembly bill on order of third reading, and will  
undoubtedly be on the calendar Tuesday or Wed-  
nesday, March 24th or 25th  
*Attitude* Favored by State Society

### Inspection by State Charities Boards of Children's Institutions

Senate Int No 228 (conc Assembly Int 236)  
*Comment* Still in committee  
*Attitude* Neutral

### Qualifications of Examiners in Lunacy

Senate Int No 263  
*Comment* Still in committee  
*Attitude* Opposed by State Society

### County Public Health Nurses

Senate Int No 283 (conc Assembly Int 399)  
*Comment* Senate bill passed March 16th,  
March 17th to Assembly Public Health Com-  
mittee  
*Attitude* Bill opposed by State Society in its  
original draft After certain amendments it was  
favored

### Health Service in Schools

Senate Int No 302 (conc Assembly Int 748)  
*Comment* Senate bill on order of third read-  
ing, Assembly bill still in committee  
*Attitude* Favored by State Society after  
amendments were made

### Vaccine Virus

Senate Int No 351 (conc Assembly Int 536)  
*Comment* Bill passed both houses Now in  
the hands of the Governor  
*Attitude* Neutral

### Injured Employee to Select His Physician

Senate Int No 380 (conc Assembly Int 570)  
*Comment* Still in committee  
*Attitude* Favored by State Society

### The Drugless Practitioner Bill (By Gibbs)

Senate Int No 473  
*Comment* March 18th, amended and recom-  
mended  
*Attitude* Strongly opposed by State Society

### Inspection of School Children

Senate Int No 586 (conc Assembly Int 580)  
*Comment* Passed Senate, now in Assembly  
Public Education Committee  
*Attitude* Neutral

### Free Choice of Physician

Senate Int No 594 (conc Assembly Int 301)  
*Comment* Still in committee  
*Attitude* Favored by State Society

### Practical Tests of Injured Persons

Senate Int No 647 (conc Assembly Int 184)  
*Comment* Still in committee  
*Attitude* Strongly opposed by State Society

### Physically Handicapped Persons

Senate Int No 671 (conc Assembly Int 868)  
*Comment* On order third reading in Senate,  
also on third reading in Assembly  
*Attitude* Neutral

### Abolishing Office of Coroner—Westchester County

Senate Int No 673  
*Comment* Bill passed both Houses and was  
signed by the Governor on March 16th Now  
Chapter 139, Laws of 1925  
*Attitude* Neutral

### Admission of Foreign Practitioners

Senate Int No 693 (conc Assembly Int 950)  
*Comment* Still in committee  
*Attitude* Neutral

### In Relation to Pharmacies

Senate Int No 632 (conc Assembly Int 802)  
*Comment* Still in committee  
*Attitude* Opposed

### Revocation of License to Practice Medicine

Senate Int No 701  
*Comment* Still in committee  
*Attitude* Neutral

### Hospital for Crippled Children at West Haverstraw

Senate Int No 786 (conc Assembly Int  
1074)  
*Comment* Still in committee.  
*Attitude* Neutral, until requested by Confer-  
ence of County Chairmen to urge that no action  
on this bill be taken for another year

### State Institute for Study of Malignant Disease

Senate Int No 787  
*Comment* Still in committee

*Attitude* Neutral, until requested by Conference of County Chairmen to urge that no action be taken on this bill by Legislature for another year

#### The Bouton Chiropractic Bill

Senate Int No 789

*Comment* Still in committee

*Attitude* Strongly opposed by State Society

#### Dissecting Material

Senate Int No 851 (conc. Assembly Int 1027)

*Comment* Senate bill still in committee, Assembly bill passed March 18th Now on order of third reading in Senate

*Attitude* Bill favored by State Society

#### Laboratory Supplies

Senate Int. No 943 (conc. Assembly Int 1167)

*Comment* Still in committee

*Attitude* Bill opposed by State Society

#### A Chiropractic Bill (By Fearon)

Senate Int No 944 (conc. Assembly Int 1423)

*Comment* Senate bill still in committee, Assembly bill on order of third reading

*Attitude* Strongly opposed by State Society

#### Foreign Licenses

Senate Int No 1123 (conc. Assembly Int 1478)

*Comment* Bill passed both houses and now in hands of the Governor

*Attitude* Favored by the State Society

#### Censors State Medical Society

Senate Int No 1176 (conc. Assembly Int 1348)

*Comment* Assembly bill passed, and now on order of third reading in the Senate

*Attitude* Favored by the State Society

#### Empowering Courts to Commit Drug Addicts to a City Hospital

Senate Int No 1378—A bill introduced in the Senate by Senator Leonard W Gibbs of Erie County, would add new section 115-a, Chapter 570, Laws of 1909, empowering courts to commit drug addicts to a City Hospital

To third reading without reference

No 1548

Int. 1378

IN SENATE,

March 16, 1925

Introduced by Mr Gibbs—read twice, and by unanimous consent, the rule was suspended, and said bill ordered to a third reading

#### AN ACT

To amend chapter five hundred and seventy of the laws of nineteen hundred and nine, entitled "An act to establish the city court of Buffalo, defining its powers and jurisdiction and providing for its officers," in relation to the jurisdiction of the court to commit drug addicts.

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Chapter five hundred and seventy of the laws of nineteen hundred and nine, entitled "An act to establish the city court of Buffalo, defining its powers and jurisdiction and providing for its officers," is hereby amended by adding a new section, to follow section one hundred and fifteen, to be section one hundred and fifteen-a, to read as follows

§ 115-a Power to commit drug addicts In addition to the jurisdiction conferred on courts of record by section one hundred and seventy-three, one hundred and seventy-four, one hundred and seventy-five and one hundred and seventy-six of the insanity law, such court, on the arrest by any peace officer of any person for unlawfully using opium, morphine, cocaine, euaine, heroin, or any of their derivatives, or any other habit forming drug or substance, or on information that any person is using the same, may commit such person to any hospital supported by the city, to be detained therein for a period not exceeding one year, or for such period less than a year as may be necessary, in the judgment of the physician in charge of such hospital, for the proper treatment and cure of such person, and any hospital supported by the city is authorized to receive and treat any person so committed

§ 2 This act shall take effect immediately

*Comment* Comment is invited

#### Statement for Marriage Licenses

Senate Int. No 1412—A bill introduced in the Senate by Senator Courtland Nicoll, of New York County, would amend Section 15, Domestic Relations Law, relative to statements for marriage licenses by striking out provision concerning venereal disease.

To General Laws Committee

Int 1412

IN SENATE,

March 18, 1925

An Act by Mr Nicoll to amend the domestic relations law in regard to applications for marriage licenses

Section 1 Section fifteen of Chapter nineteen of the laws of 1909, entitled "An act relating to the domestic relations constituting chapter fourteen of the consolidated laws," as last amended by chapter 317 of the laws of 1921, is hereby amended to read as follows

15 Duty of town and city clerk It shall be the duty of the town or city clerk when an application for a marriage license is made to him to require each of the contracting parties to sign \* \* \* maiden name of mother, country of birth, number of marriage [From each A statement in the following words "I have not to my knowledge been infected with any venereal disease, or if I have been so infected within five years I have had a laboratory test within that period which shows that I am now free from infection from any such disease"] (Remainder same as old law)

*Comment* No comment

## LEGISLATIVE INVESTIGATION OF ILLEGAL PRACTITIONERS

The following resolution was introduced by Senator Love, March 17

*Whereas*, it is of common report that medicine is being extensively practiced throughout the State of New York by graduates of low-standard institutions, who have obtained diplomas from sources not recognized by New York State authorities and that the general practice of such so-called physicians has become so great as to jeopardize the public health of the State,

*Be It Resolved* (if the Assembly concur), That a joint legislative committee is hereby created to consist of three members of the Senate to be appointed by the temporary president of the Senate, and five members of the Assembly, to be appointed by the Speaker of the Assembly, to inquire into and ascertain the following facts

If public health has been injured by the activity of self-styled medical institutions and "diploma mills," if graduates of any such low-standard institutions are employed by the State Public Health Service or any other branch of the State government, if the standing of the State medical institutions and of our medical profession generally has been injured in other States by the action of such self-styled medical institutions and diploma mills, if graduates of such institutions and diploma mills are now offering themselves as practitioners of medicine in the State of New York, if all the laws and requirements as to registration are being observed by practitioners of medicine in the State of New York, if any institutions giving degrees in medicine in the State of New York, are issuing diplomas or degrees to persons without sufficient

knowledge and training as to legitimately entitle them to such diplomas or degrees, to ascertain from the United States Government officials if the mails have been used by such self-styled medical institutions and organizations known popularly as diploma mills for purposes of fraud in connection with the sale of degrees or diplomas in preparation for medical practice, and to inquire to the fullest possible extent as to the legitimate transactions of all institutions or schools issuing such diplomas or degrees

Such committee shall choose from its members a chairman, may employ a secretary, counsel, stenographers and such other employees and assistants as may be necessary and fix their compensation. Such committee shall have power to sit within and without the city of Albany and within and without the State of New York, having authority to subpoena and compel the attendance of witnesses, including the production of any book, paper, document or record pertaining to the subject of its investigation and shall have and possess generally all of the powers of a legislative committee

Such committee shall report to the legislature of nineteen hundred and twenty-six the result of its findings, together with such remedial legislation as it may deem warranted in suggesting

*Be It Further Resolved* (if the Assembly concur), That the actual and necessary expenses of the committee in carrying out the provisions of this resolution, not exceeding the sum of thirty thousand dollars (\$30,000), be paid from the legislative contingent fund upon vouchers audited and approved by law

To Finance Committee

# State Department of Health

## ANOTHER CHILD MARTYR PROMOTES THE CAUSE OF DIPHThERIA IMMUNIZATION

A child, ten years of age, recently died of diphtheria in one of the cities of the State. This child was a pupil in a private school where immunization had been offered some time previously. At that time, however, the school principal had not consented that the work should be done, after the child died, however, the health officer again brought the subject to the attention of the principal. Realizing that one of the chil-

dren had died from diphtheria, probably unnecessarily, he then accepted the health officer's proposal to immunize the children in the school. Consents for the immunization were obtained from the parents of 102 of the 160 pupils who constitute the school. The health officer has recently reported that the work of immunization among those who presented the consents is practically complete.

## BUFFALO BETTER BUSINESS COMMISSION EXPOSES "MEDICAL SPECIALISTS'" METHODS

The Buffalo Better Business Commission, a non-stock, non-profit organization of business men organized for the purpose of protecting the public from fraud and deceit in the advertising and selling of merchandise, in its bulletin for January 5, gives an expose of the methods employed by a group of men posing as specialists in the treatment of diseases of man. Representa-

tives of the commission visited the offices of these men and had diagnoses made of their "condition." In one case a report was made to the patient of the results of an urinalysis when a sample of urine had not been submitted. The report states that newspapers which have been notified of the facts of the investigation have since refused the advertising of the firm.

## SOME CHURCHES REALIZE THEIR RESPONSIBILITY IN THE CONTROL OF VENEREAL DISEASES

Recently a church invited a physician from the Division of Venereal Disease Control to address the men in its "Problem Class." The speaker discussed the public health aspect of gonorrhea and syphilis and pointed out the responsibility of the church in their control. The men were so well impressed with the practical measures suggested for the reduction of the inci-

dence of these insidious diseases, and with their own opportunity actively to participate in the State program for their ultimate eradication that they requested the lecture be followed by a series of talks in order to help the men to organize as a church group and also to prepare them individually for the responsibility of instructing their own boys along sex hygiene lines.

## GRANVILLE PLANS BETTER NURSING SERVICE

At a combined meeting of the health and educational authorities of the village of Granville, Washington County, and the Chairman of the Committee on Health Promotion, it was decided that the present nursing service of the village

was inadequate, and that it was desirable that the schools and the village should each have a full-time nurse. The various boards represented at the meeting have been requested to take favorable action on the matter.

## WASHINGTON COUNTY SUPERINTENDENT IMPROVES SCHOOL SANITATION

The school superintendent of the second district in Washington County has been making a drive in her district to improve the sanitary condition of school houses.

She reports that no common drinking cups or dippers are now to be found in her entire district. A majority of schools are using individual

paper drinking cups, the rest individual metal cups. All outhouses have been thoroughly cleaned and repaired and several new ones have been built. In several of the schools complete rearrangement of seating has been accomplished in order to furnish proper light for the children and conserve their sight.

# NEWS NOTES

## 35TH REUNION CLASS OF 1890

The Class of 1890, Bellevue Hospital Medical College, dined at the Hotel Astor on the evening of March 10, celebrating the thirty-fifth anniversary of graduation. There were present Chancellor Brown, Professor Frederic S. Dennis, the only surviving member of the faculty of 1890, and Dr. Robert J. Carlisle, Drs. Reginald Sayre and Henry Mann Silver, who were instructors at that time. Dr. Thomas Manning of New Rochelle presided. The newly elected officers were Dr. Edward B. Hickel, Pittsburgh, President, Dr. Samuel G. Tracy, Vice-President, Dr. Henry W. Frauenthal, Treasurer, and Dr. John E. Virden, Secretary and Historian. Others

present were Drs. Charles W. Banks, East Orange, New Jersey, Clarence S. Kurtz, Malvern, Pennsylvania, William H. Murray, Danbury, Connecticut, Erasmus A. Pond, Brooklyn, Ernest E. Schierge, Scotch Plains, New Jersey, Paul H. Fairchild, Frank Hollister, N. B. Van Etten, and Robert J. Wilson, New York.

One hundred and forty-four men graduated in this class, sixty-four of whom still keep in touch with the secretary. A dinner has been held every March 10th for the last eleven years in the yacht room of the Astor and the room is engaged for ten years more.

## ALUMNI ASSOCIATION OF FORDHAM HOSPITAL

The Alumni Association of Fordham Hospital held the Fourth Annual Dinner on March 14th at the Concourse Plaza Hotel. One hundred and fifteen of the former internes and their guests enjoyed a very delightful evening. Dr. Fred Schaeffer presided and made the only speech of the evening.

The Fordham Hospital, now housed in a modern building accommodating three hundred patients, facing Bronx Park on the Southern Boulevard, is thirty-three years old. It was started by Dr. Robert A. Joyce and opened by the Department of Charities and Correction in 1892 in a

remodeled residence at the corner of Valentine Ave. and 188th Street.

It is interesting to note that this was previously the house of three physicians, Dr. Eugene E. R. Peuguet, 1861 to 1879, Dr. Havilah Sprague, 1868 to 1874, and Dr. John H. Eden, 1880 to 1890, and since the Fordham Hospital moved to larger quarters, this same site, with added property, has been occupied by the Union Hospital.

The ground is truly hallowed by sixty-four years of altruistic services.

## PROGRESS IN NEW MEDICAL CENTER

The work on the Medical Center of New York City which was initiated through the combined efforts of the Columbia University and the Presbyterian Hospital in the City of New York, is making steady progress. The Joint Administrative Board reports that the excavations for the combined School and General Hospital Building is now advancing rapidly, and that contracts for the steel, brick, sand, and gravel have been awarded, and that work on the foundation will commence May 1st.

There have recently been two important additions to the Center. The Babies' Hospital and the Neurological Institute of New York have both signed agreements with the Joint Administrative Board and will receive land for the erection of their new institutions as a part of the Medical Center.

The Babies' Hospital which is at present located at 55th Street and Lexington Avenue, is unique in its field as it is the only institution which up to this time has devoted its efforts ex-

clusively to children under four and a half years of age. It is well known also through the work of the late Dr. L. Emmet Holt, and its research work in feeding and surgery of infants. In the new Center the scope of the Babies' Hospital will be expanded to include older children.

The Neurological Institute of New York which has just completed its fourteenth successful year is equally unique in the medical field. It is the first cooperative effort of a neuropsychopathic group in America to meet the growing need for treatment and study of the neurosis and early mental disorders among the working classes. The growing menace of this increasing group of nervous disorders has been met with their limited facilities, not only by treatment but by research and the training of physicians and nurses in the care of this particular type of individual. Both institutions will not only bring to the Center a well organized unit which will contribute much to the success of the

Center, but through the change will find an enlarged expression for their endeavors

The Joint Administrative Board has been augmented by the addition of the president of the Babies' Hospital, John Sherman Hoyt, and the president of the Neurological Institute, Robert Thorne. The Joint Administrative Board is at the present time composed of General William Barclay Parsons, Chairman, Dean Sage, Robert

W de Forest, Walter B James, Edward S Harkness, John G Milburn, John Sherman Hoyt, Robert Thorne, with Dr William Darrach, Dean of the Medical School, acting in an advisory capacity, and Dr C C Burlingame as Executive Officer

THE JOINT ADMINISTRATIVE BOARD,  
17 East 42nd Street,  
New York

## AN EXPERIENCE WITH CHIROPRACTORS

It is not sufficient that the campaign against cultists be limited to one or two medical journals. There should be more publicity of the type which will reach the lay public, serious, severe, and unrelenting. If the chiropractors and other cults may use the lay press for their purposes, with frequent references of ridicule towards the medical profession, there is no reason why we should not do the same.

May I relate a personal experience with chiropractors? A young woman, in her late twenties became a patient of mine. A late evening hurry call brought me to the bedside of this young lady, whom I found in a condition very near the end. She sat crouched up in bed gasping for breath, cyanosed and coughing up bloody, frothy mucus, pulse almost imperceptible and irregular, an attack of cardiac decompensation as my readers will recognize. By a miracle she survived the night. She had suffered all the previous day, received chiropractic treatment without relief, and the seriousness of the condition becoming apparent to friends and neighbors, it was deemed advisable to call a physician. Seemingly the shadow of the undertaker was also apparent. Now, after two years of medical care at home and in hospitals, treated by myself and other physicians, she is quite well but not active as she once hoped to be in the capacity of a busy and flourishing lady chiro.

This young lady, by the way still a friend of mine, had shortly before the tragic occasion which caused our acquaintance, graduated a full-fledged Palmer chiropractor. A frail, sickly girl, having the strength of a sparrow, earnest and sincere but lacking in experience and practical knowledge, desiring a life calling, and means of independence, had decided to become a chiropractor. Might not publicity have avoided

this? She went through her course, despite several cardiac attacks while in Davenport, which by the way were "treated and cured" by spinal manipulation. And the chiro's say they do not practice medicine. But this is not at all in regards to the physical defects of this young woman, for she had besides a marked and advanced spinal deformity, a poor little hunchback. In credit to the chiro's let me say here, they did not attempt to cure her spinal deformity. The case of this young woman is authentic, histories can be obtained from several hospitals, and she has likewise been examined and treated by several of our prominent physicians.

The writer could go into considerable more detail, not only in reference to the above case, but also about a poor little infant, thin, emaciated and running temperature, with active tuberculosis of the spine as demonstrated by the X-ray. As the mother pitifully told us, whenever the chiropractor pounded the baby on the back, it shrieked in pain. There was also a case of violent mental disease housed in a chiropractic institute.

This issue of the chiropractor must be combated. We are glad to deal with any group that is open to reason. He who treats disease by way of the spine, is practicing medicine, and for this privilege he must accept the Oath of Aesculapius, and earn his license, even as you and I have. The writer believes that Medical Registration will help along these lines, but not without continuous publicity, directed towards the public, and so educating the people, that they shall know that a licensed and registered physician is the only one qualified and permitted to treat disease.

PHILIP KASSEN, M D,  
4515 14th Ave., Brooklyn

## A CORRECTION

My attention has been called to a misstatement which was made in my article on "The Treatment of Lobar Pneumonia with Pneumococcus Antibody Solution," which appeared in the New York State Journal of Medicine, March 6th, 1925. The last paragraph on page 357 begins with a statement that "During the last few months we have returned to the intravenous method of administering antibody solution." In

this sentence "months" should read "weeks." During this time several lots of antibody solution were sent us by Dr Huntoon for testing on patients in the ward. Some of these lots when injected intravenously produced no reaction whatever. Other lots caused thermal reactions similar to those described in our previous articles.

RUSSELL L CECIL, M D

### SUSPECTED POLIO PROVES TO BE BROKEN ARM

In your issue of March 13th, 1925, under State Department of Health Notes there is recorded an interesting case under the caption "Suspected 'Polio' Proves to Be Broken Arm." I would like to record an almost identical case which occurred during the big epidemic several years ago.

A baby was brought to a dispensary in New York and, because the child could not move his leg, it was regarded as a case of poliomyelitis. At once the authorities had an ambulance summoned to take the case to an isolation hospital where cases of poliomyelitis were being treated. While awaiting the ambulance, someone suggested that an X-ray examination would be advisable for possible early tuberculosis of the hip joint. The X-ray examination was found to be negative for this condition.

By this time the ambulance had arrived. Something in the appearance of the femur made me suspicious of a lesion lower down, so that I insisted on holding the ambulance while I made a lateral X-ray examination of the entire leg, and, sure enough, we found a fine linear fracture of the femur without any displacement of the fragments.

Needless to say, the ambulance was sent back to the Contagious Disease Hospital without a patient, and the child was saved from the possibility of contracting poliomyelitis. A proper splint was applied to the leg and the child made a good recovery.

New York University

### RICHMOND COUNTY MEDICAL SOCIETY

On Wednesday evening, March 11th, 1925, in lieu of the regular meeting, a testimonial dinner was given to Dr. Walker Washington by the Richmond County Medical Society at the Staten Island Masonic Club in commemoration of his fortieth year of active practice. Fifty members of the Society were present.

Dr. Washington graduated in 1885 and has been practicing medicine at Tottenville since that date. Dr. Washington described his early days here, stressing the difficulties of travel, both from

the standpoint of poor roads and that his first horse functioned only on three legs.

Dr. Soldini made a plea that doctors should not disparage the efforts of their contemporaries as it caused the public to lose confidence in the entire medical profession. He said that new advances in the science should be explained to the patients and charlatanry exposed.

Other speakers were Drs. Jessup, Coonley and Bryan. Dr. E. Warren Presley, President of the Society, acted as toastmaster.

CHARLES RIEGER, Secretary

### MEDICAL WOMEN'S NATIONAL ASSOCIATION

The women physicians attending the A. M. A. Convention in Atlantic City in May will have their headquarters at the Marlborough-Blenheim Hotel. On Wednesday, May 27, they will have a banquet at the Ambassador at \$5.00 a cover. Subscriptions, accompanied by check, should be received by Dr. Clara K. Bartlett, 4301 Atlantic

Avenue, Atlantic City, N. J., not later than May 25.

The Medical Women's National Association will hold its annual meeting May 25-26, 1925, at the Marlborough-Blenheim Hotel, Atlantic City, N. J.

## GORGAS MEMORIAL

### I WHAT IS THE OBJECT OF THE GORGAS MEMORIAL INSTITUTE?

This Institute, incorporated October 21st, 1921, has for its object and purpose the following

To conduct, assist and encourage investigations in the sciences and arts of hygiene, medicine and surgery and allied subjects, in the nature and causes of disease and the methods of prevention and treatment, and to make knowledge relating to these various subjects available for the protection of the health of the public and the improved treatment of disease and injury, particularly as applied to Tropical and Preventive Medicine

### II HAS IT A CHARTER?

Yes, it was incorporated under the laws of New Jersey, October 21st, 1921, after five informal conferences held during the period from January 31st to October 21st, 1921

### III HAS IT BY-LAWS?

Yes These were drafted by the Hon John Bassett Moore and adopted at a meeting of the incorporators held in Philadelphia, October 26th, 1921 At this meeting an Executive Committee was appointed, three members of which were to constitute a Finance Committee

### IV WHAT IS THE TABLE OF ORGANIZATION?

In accordance with the by-laws, the officers, elected by the Board of Directors, consist of President, one or more Vice-Presidents, Secretary and Treasurer There is a Board of Scientific Directors, an Executive Committee, a Finance Committee, Committee of Publicity and Education, State Governing Committees and County Committees The by-laws provide for the election of officers and appointment of committee members and their successors

### V HOW ARE FINANCES HANDLED?

In accordance with the by-laws, by the finance committee consisting of three members of the board of directors elected by the board at the annual meeting At a meeting of the finance committee, August 27th, 1923, Mr Geo M Reynolds was elected Treasurer, who has custody of funds All bills must be vouchered and signed by the Secretary or a member of the Finance Committee and no bills are paid except those incurred under the authority of the Executive Committee Books and accounts are open at all times to the inspection of the Board of Directors Accounts are subjected to annual audit by a person or persons not connected with the board

### VI IS THERE NOT A DUPLICATION OF WORK IN PREVENTIVE MEDICINE WHICH IS ALREADY BEING DONE BY EXISTING ORGANIZATIONS?

This is a personal health educational campaign directed to the public and the family physician and is nation wide in its scope The directors cannot find that any other organization specializes on personal health education The Gorgas Memorial does not plan to replace any existing health agency, but to augment and assist all methods now used in health education

### VII HAS THE GORGAS MEMORIAL THE SUPPORT OF REPRESENTATIVE MEMBERS OF THE MEDICAL PROFESSION?

Yes It has been formally endorsed by the House of Delegates of the American Medical Association, which has recommended that its subsidiary and county societies throughout the United States co-operate in its development All medical members of the Board of Directors and of Committees are physicians occupying the forefront in American medicine Over 1,400 physicians throughout the nation have already become members of State Committees through which health education will be conducted The American College of Surgeons and ten other national health organizations have officially endorsed the work

"Health is a saleable commodity and there is an eager market for it," said Dr Herman N Bundesen, Chicago Commissioner of Health, recently at a session of the congress on medical education of the American Medical Association

Dr Bundesen pointed out the obligation which the medical profession and scientific health organizations have to the American public

"The primary function of public health," the Commissioner said, "must be concerned with man-made laws to safeguard the masses Its chief concern is for communicable diseases—all those which can be controlled by legislation But mere laws to enforce health will not create it Good health must come from desire stimulated by knowledge"

"Since the health of a community is the combined health of the individuals composing it, such a nation-wide agency as the Gorgas Memorial Institute, to which I have the honor to belong, is a potent factor Its value lies in combating wrong habits of living which result in such maladies as heart disease and Bright's disease, and in supplementing the work of public health

"In securing closer co-operation between physicians of the country and the individual, the Institute is doing a far-reaching work by establishing scientific medicine as the best authority in health matters"

# THE DAILY PRESS

Articles criticizing vaccinations often appear in the public press, and evidently are making somewhat of an impression, judging by the circulation of the papers which make a specialty of such articles. One New York paper of this kind mixes the alleged impressions of a murderer awaiting execution with love advice and anti-medical propaganda. It is questionable how much effect these papers have on the medical thought of the public. The tendency of the times seems to be to give publicity to the unpleasant side of life. The moving pictures stress the inhumanity of the heroine in the hands of the selfish villain, the preachers deplore the darkening of the moral skies, and the anti-medical propagandists dwell upon the unpleasant side of medicine.

The calamity howler is always with us—always has been and always will be. He likes to hear the sound of his own voice, and he gets a crowd to listen out of curiosity. Modern folk, like the people of Athens, are overwhelmed with a desire to tell or hear some new thing. The usual and the common are not news. Curing people with diphtheria antitoxin and preventing smallpox with vaccine are ordinary events which are almost commonplace. But fatal anaphylaxis from antitoxin, and a sore arm in a careless boy who has been vaccinated, are decidedly uncommon and are therefore featured, for they draw a crowd and help to sell newspapers.

When the great majority of newspapers throughout the land give large amounts of space to medical news and reports of Departments of Health, it is good business for a few papers to print articles in opposition to scientific medicine. The opposing fellow often gets a hearing simply because he is in opposition. The public likes a fight, and some newspapers welcome a furious debate because it is unusual and sensational.

The fellow in opposition to scientific medicine always has the advantage in a debate or abuse, because he is not hindered or restrained by truth. He acts as if he had no need of truth, and he would not be convinced by truth if it were demonstrated to him.

Psychiatrists tell us that whatever goes into the brain by any other route than reason cannot be removed by reason. We wonder if medical men should take any notice at all of anti-vaccination propaganda, and of other anti-medical stories. We have been tempted to quote from a series of articles in a New York daily purporting to tell how smallpox vaccine is made. The articles were truthful to the extent that they described the processes of manufacture from the inoculation of calves to the final sealing of the packages, and the adver-

tising propaganda by which the product was brought to the attention of physicians and boards of health. But here is the joker. In every paragraph the greswome aspects of the process were magnified out of all proportion to the rest of the process. The bleating of the calves, the blood, the apparent joy of the microscope technician in examining a gory specimen, all these were set forth in a way to indicate that the physicians and technicians are hard-hearted demons. Of course such a write-up defeats its own object, and reveals the unreasonableness of the writers. Still some people will believe what is written and will create trouble by an insistence on their beliefs.

We are inspired to make these editorial comments by an article in the *Batavia News* of March 11, which we here quote in full.

"Vaccination provides certain immunity from smallpox. There is always the possibility of men, women and children coming in contact with a person having the disease and contracting it. Why not, therefore, be vaccinated? A bulletin from the state department of health cites this case in point.

"*Health News* of February 2d carried an item mentioning a fatal case of smallpox in a school teacher. An interesting feature of this case has just been brought to our attention by the health officer of the municipality in which the teacher lived. Following the teacher's death, mothers of two pupils in her class independently reported to the health officer that just before Christmas they had told the teacher that their children were to be vaccinated during the holidays. The teacher strongly urged against it on the ground that it 'was a medieval custom, was harmful to the welfare of the child, and that deaths were occasionally caused by such vaccinations.' On January 12th this teacher died of smallpox. Although she took her own advice, fortunately the mothers of her pupils did not."

"More than 200 pupils in the schools of Batavia recently have been vaccinated, and the parents of more than 400 have given consent to the vaccination of their children."

The fallacy of half truths is illustrated in an article in the *Brooklyn Citizen* of March 12, in which a chiropractor active in politics says:

"The Fearon Chiropractic bill in its amended form will be an impossible piece of legislation. Under the provision preventing the chiropractors from handling communicable diseases, the public would be denied the services of chiropractors in cases of influenza. When it is considered that during the epidemic in 1920, the deaths from

this disease under medical men were one out every seventeen cases handled while the drugless practitioners lost only one out of every 886 cases, the seriousness of this amendment can easily be appreciated

"It is well for the public to know that Dr Mathias Nicoll wishes all practitioners driven out of New York State.

"Realizing that the legislators are determined to enact some type of law licensing us, the State Health Commissioner is seeking by indirect means to prevent us from practicing under the terms of our own law. This amendment on communicable diseases places in his hands the power to prevent us from handling all diseases for it is the State Health Board which decide as to what diseases are communicable."

We are surprised that chiropractors and other drugless practitioners should have lost even one out of 886 cases of influenza that they handled during the epidemic. The principal element in our surprise is that any one who has influenza should put himself in the hands of a chiropractor, but it is evident that at least 886 persons entrusted their lives to the cultists.

We wonder how many of these people would have consulted the chiropractors if those practitioners had not made positive claims of their ability to diagnose and cure cases of influenza?

We wonder, too, why any chiropractor allowed a case to die on his hands? We have talked to chiropractors who are endowed with considerable worldly wisdom, and most of these practitioners say that they are anxious to drop every acute case that gets worse, for they are quite willing that physicians should get the notoriety of having cases die on their hands. Of course chiropractors have low death rates. The fact that they have any death rates at all is a confession of guilty negligence on their part.

The daily newspapers are unable to give prominence to follow-up stories of a movement after it has become a routine matter. The natural course which a movement takes is that at the beginning it blazes forth on the front pages with big headlines and illustrations. In a day or two it dwindles to a paragraph among inconsequential items about dinner parties and new buildings. Very little is said about the immense amount of detail work of investigation, conditions and of planning their remedies. We have tried to follow up conditions which we have described, and have often had great difficulty in getting information from the daily newspapers.

In our Daily Press of January 23rd, we commented on the ban against the importation of chickens into New York City on account of chicken plague. The papers have said very little regarding the further action taken by the Department of Health of New York City, or of the course of the epidemic.

The New York Times of March 12 contains an inconspicuous item two and a half inches long which reveals that an immense amount of work has been done on the epidemic throughout the eastern part of the country. The item is as follows:

"Dr Frank J. Monaghan, Health Commissioner, announced yesterday that the Board of Health would make radical changes next Wednesday in the live-chicken embargo, which has been in force for three months because of the chicken-plague.

"The Commissioner said the embargo against North and South Dakota, Missouri, Kansas, Iowa and Nebraska would be lifted, but that against Illinois and Indiana would be continued. He expected to see shipments into this State from Pennsylvania and Ohio prohibited.

"These changes, he said, had been agreed upon yesterday at a conference called by the Department of Agriculture of this State. Representatives of this State, New Jersey and Connecticut, New York City and Jersey City, and also of the commission merchants, were present. Adoption of the changes will make quarantine regulations uniform in New York and New Jersey and simplify enforcement. The States from which the embargo is to be lifted have rectified objectionable conditions."

The New York Evening World of March 12 uses the term "Prophetic" medicine by which it means the branch of medical practice which deals with tendencies toward sickness and the means of preventing their development. The World publishes a long description of a periodic health examination clinic conducted by a Post Graduate Medical school. The unique feature that is described is a booklet that is filled out by the patient with his own impressions about himself. The following quotations from the booklet indicate the scope of the patient's self-examination:

"My health is excellent—Good most of the time—Only fair—Rather poor—Quite bad—If it wasn't for I would be fine

"Customarily I am quite rugged—Very strong—Fairly strong—A little weak—Tire easily—Very weak. In my work I am very successful—Doing—Well—Holding my own—Indifferently well—Unsuccessful. I worry about my work, however—A great deal—Somewhat—Don't give it a thought at night. My work is administrative—Professional—Clerical

We believe it to be conducive to making the patient's answers full and truthful that he has before him the various degrees of the conditions on which he is questioned. This form of questionnaire is worthy of consideration by those who are devising blank forms for health examinations.

# BOOK REVIEWS

**ACIAL SURGERY** By H P PICKERILL, CBE, MD, MS Introduction by Sir W ARBUTHNOT LANE, Bart, CB, MS William Wood and Co, New York, 1924 Price, \$6 50

The Great War was responsible for several important and epoch making forward steps in the science and art of surgery, without which stimulus progress would undoubtedly have been much more tardy, and perhaps no greater advance may be noted than in the art of the plastic repair of facial defects due to the destructive effect of war injuries

From the necessity born of the injuries of war there arose a group of surgeons at Queen Mary's Hospital, Sidcup, to which place innumerable facial injuries were sent for relief, and where a vast amount of experience was acquired, who became wonderfully adept in facial plastic surgery In charge of the New Zealand Section was found H P Pickerill, the author of this work. Divided in three sections, it deals with (1) the principles and technique of plastic surgery, (2) Military Facial Surgery, and (3) Facial Surgery in Civil Practice.

The principles enumerated in this work appear to revolutionize the art of plastic surgery, and of especial interest may be mentioned pressure skin grafts, tube flaps, epithelial inlay, and caterpillar tube grafts, etc The subject matter of military surgery is fully illustrated and described, with case reports from the hospital at Sidcup, which illustrate the possibilities of the work and as a direct result of which have broadened the field and possibilities of facial surgery in civil practice, in making possible greater radicalism in the excision of malignant growths, the repair of congenital defects, and the remedy of destructive injuries

This book is a valuable contribution to the field of plastic surgery, and of profound interest to and a necessity for any surgeon attempting work in this special line

The methods and principles laid down also will apply in such congenital defects as hare-lip, cleft palate, nasal deformities, facial paralysis, absence or atresia of the vagina, and this work will bear careful reading and study It is not too much to expect that former methods will be discarded, when the possibilities of the new become known

ROGER DURHAM

**HUMAN CONSTITUTION A CONSIDERATION OF ITS RELATIONSHIP TO DISEASE.** By GEORGE DRAPER, MD Octavo of 345 pages with 208 illustrations and 105 tables Phila and London, W B Saunders Co, 1924 Cloth \$7 50

The author states that the object of this book is threefold "First, it attempts to present to the physician a dependable method for studying morphology, second, to point out the inadequacies of the existing observational and descriptive procedure, and third, to emphasize the interest and importance of the study of the Human Constitution"

This study has been made, apparently to determine certain basic constitutional differences, which are associated with various forms of disease It is the result of a series of studies made at the Constitutional Clinic of the Presbyterian Hospital in New York A small group of patients suffering from about six diseases were studied by various workers skilled in their own particular branch of science. Anthropometric determination and indices were calculated and the curves plotted The author has in mind a possibility that the anthro-

pological factors and the hereditary tendencies of an individual may have a significance in the pathological diagnosis If this is true then a closer study of the personality will be of great assistance in clinical medicine. Numerous interesting relationships are brought out even in this small group of cases, although the number of cases are much too small to draw generalizations This study is to be continued by Dr Draper and his group of workers and further developments are expected Clinicians who are not acquainted with the methods used in this type of research will find this book exceedingly interesting

O C P

**PATHOGENIC MICROORGANISMS A Practical Manual for Students, Physicians and Health Officers** By WILLIAM HALLOCH PARK, MD, ANNA WESSELS WILLIAMS, MD, and CHARLES KRUMWIEDE, MD Eighth Edition, enlarged and thoroughly revised Octavo 811, 211 engravings, 9 full-page plates Phila and New York, Lea & Febiger, 1924 Cloth, \$6.50

This is one of the standard works on bacteriology and needs no recommendation There have been some notable recent advances in bacteriology and these have been incorporated in the present edition They include experience with diphtheria immunization, new discoveries about scarlet fever and the pathogenic anaerobes, measles, typhus and tularemia Several sections, including those on paratyphoid and dysentery, have been rewritten There is an extensive list of culture media. One of the valuable features of this work is the portion dealing with the practical use of biologicals

E. B SMITH

**GYNECOLOGY, MEDICAL AND SURGICAL.** By P BROOKE BLAND, MD, Assistant Professor Gynecology, Jefferson Medical College. 644 Illustrations, 43 colored text figures, 12 insert plates F A. Davis Co, Phila, 1924 Students' Edition, \$11 00 net, Library edition, two volumes, \$14 00 net.

In this large, well illustrated volume, the author has covered gynecology in its medical and surgical aspects in a most thorough manner A large amount of space is devoted to the medical or conservative treatment of disease of the pelvic organs and, therefore, the book may be of special value to the general practitioner, as well as to the specialist.

The chapters on anatomy, etiology, symptomatology, and diagnosis are complete, concise and very readable.

Preoperative preparation and postoperative complications are covered thoroughly, while the chapter on therapeutics gives a wealth of detail Here are clearly discussed such subjects as organotherapy, proteinotherapy and the gynecological uses of and indications for radium and X-ray

Disorders of function, malformations, displacements inflammations and hemorrhage are thoroughly covered in chapters by themselves and the remainder of the volume is devoted to a consideration of all the phases of tumors of the pelvic organs

The author is to be congratulated upon the completeness of his work

W S SMITH

MEDICAL CLINICS, NORTH AMERICA

Published every other month by the W B Saunders Co Phila and London Per Clinic Year (SIX ISSUES) Cloth \$16 00 net, paper \$12 00 net

Vol VIII, Number 1, July, 1924 (New York Number)

Thirty one articles in this number many by personal friends, make it difficult for the reviewer to choose any

special paper for praise. It is only necessary to see the list of contributors to know that a complete medical survey is included in this issue which upholds the standard of these clinics. The reviewer recognizes the falsity of the statement "a prophet is not without honor save in his own land." Read this issue and prove it.

H. M. M

Vol. VII No. 5, May, 1924 (McGill University Number)

This issue of the *Clinics* contains many instructive, interesting articles in which the field of medicine is well covered. Henderson gives a carefully prepared paper on "The Successful Treatment of Asthma" and Related Conditions, on which there is still so much room for controversy. The circulatory system is covered by a number of papers on some of the various heart conditions. Mackay's paper on "Pituitary Dysfunction" tells much of this gland, and other conditions of the nervous system are presented by different writers. This issue contains many articles of value.

H. M. M

#### SURGICAL CLINICS, NORTH AMERICA

Volume IV, No. 3, June, 1924 (Chicago Number)  
Published every other month by the W. B. Saunders Company, Phila. and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net.

The Chicago number covers so many subjects in the various departments of Surgery, and by so many contributors, that it would take up too much space to review them even briefly, and do justice. Suffice it to say, that all the topics are as interesting as they are instructive and important, whether it is the cases of abdominal tumor with the usual difficulties in diagnosis by Dr. Bevan, or the treatment of cancer by cautery by Dr. Ochsner, or the gynecological operations by Dr. Watkins, or genito-urinary conditions by Dr. Eisendrath, or fracture-work by Dr. Speed.

HERMAN SHANN

Volume IV, No. 4, August, 1924 (Cleveland Clinic Number)

The discussion by Dr. Crile on the factors that govern the surgical mortality of operations for hyperthyroidism is most enlightening. Even in the hands of this famous surgeon, certain types are hopeless with or without operation, and these are cases with delirium, or with persistent nausea and vomiting.

Another article by Dr. Crile is on the excellent results he has obtained in cases of carcinoma of larynx, citing a number of cases alive and well many years after laryngectomy.

The other contributions are all from the Cleveland Clinic, and cover a variety of subjects well worth reading.

HERMAN SHANN

MANUAL OF DISEASES OF THE NOSE, THROAT AND EAR. By E. B. GLEASON, M.D., LL.D. Fifth Edition thoroughly revised. 12mo of 660 pages with 212 illustrations. Phila. and London, W. B. Saunders Co., 1924. Cloth, \$4.00.

The fifth edition of Gleason's well known book is a very practical manual. Intended as it is, for students and general practitioners it is very acceptable for it abounds with practical suggestions that are given very little space or consideration in similar text books. The reviewer would recommend it as the starting point for the embryo specialist for its contents are both simple and fundamental. The formulary which carries with it instructions for the proper use of the prescribed medication is a distinctive feature and of value.

M. C. M

OPERATIVE SURGERY. Covering the Operative Technique Involved in the Operations of General and Special Surgery. By WARREN STONE BICKMAN, M.D., F.A.C.S. Vol. 5. Octavo of 880 pages with 1118 illustrations. Phila. and London, W. B. Saunders Co., 1924. Cloth, \$10.00 per volume. Sold by subscription only (To be complete in six volumes with desk index.)

The excellency and completeness of this splendid work is maintained in volume five, which contains the chapters on the kidneys, ureters, bladder, and scrotum. All the operations on these organs are very well described. The text is concise and to the point, and yet ample. Every step is clearly outlined by the text and also by a large number of excellent illustrations, most of them original. This volume should be read by every surgeon working in this field.

N. P. RATHBUN

COSMETIC SURGERY, THE CORRECTION OF FEATURAL IMPERFECTIONS. By CHARLES CONRAD MILLER, M.D. 140 illustrations. F. A. Davis Co., Phila. 1924. Price \$4.00 net.

This work contains twenty-two chapters devoted to the correction of featural imperfections. The work is well and profusely illustrated. Here one may learn how to remove doublechin, eradicate wrinkles and perform other operations which the beauty doctor may be called upon to do.

METHODS IN MEDICINE. The Manual of the Medical Service of George Dock, M.D., ScD, formerly Professor of Medicine, Washington School of Medicine, formerly Physician-in-Chief Robert A. Barnes Hospital, St. Louis. By GEORGE R. HERRMANN, M.D., Ph.D., Instructor in Medicine, University of Michigan, formerly House Officer, Peter Bent Brigham Hospital, Boston, formerly Assistant in Medicine, Washington University, formerly Resident Physician Robert A. Barnes Hospital, St. Louis. Illustrated. The C. V. Mosby Company, 1924, St. Louis. Price, \$6.50.

This manual includes the instructions to the staff, the responsibilities, the Hospital rules, the outline and methods of procedure in different conditions, the laboratory procedures, the general treatment of diseases and use of drugs, together with the history forms used on the service of Dr. George Dock at the Barnes Hospital, St. Louis. It is complete in every detail and indispensable to any one who is interested in the management of any service in a modern hospital. It is well written, readable, well-printed and valuable.

H. M. M

THE MOTHERCRAFT MANUAL, by MARY L. READ, B.S. illustrated. Little, Brown and Co., Boston, 1922.

This book is indeed excellent, not only in the choice of its name, but more important in the instruction provided. It is sound physiologically and psychologically. Its frequent diet lists as well as charts showing analysis of the various foods its frequent outlines for daily routine physical examinations its review of the common causes of fretfulness malnutrition etc. makes it indeed a most valuable book, not only for the mothers but the nurses and doctors as well.

The illustrations are good and the charts are well arranged.

It has one fault and that is that only the educated woman can use it.

G. W. P

**DOMICILARY TREATMENT OF PULMONARY TUBERCULOSIS**  
By F. RUFENACHT WALTERS, M.D. Second Edition  
Octavo of 288 pages New York, William Wood & Company, 1924

Your reviewer regrets to state that he found this a rather uninspiring text. In the arrangement of the subjects discussed there is a total lack of continuity of idea and expression. Much of that written has been stated before, and in much better form. There is a great deal of needless repetition and considerable time spent in the discussion of either obsolete or irrelevant matters such as that on the value of the Opsonic Index, and that on innumerable drugs that are supposed to aid recovery in Pulmonary Tuberculosis. The book abounds in footnotes devoted to references and bibliography, the dates of most of which run anywhere from 1881 to 1910. Of recent valuable contributions to the study of Tuberculosis, the book is strikingly deficient.

FOSTER MURRAY

**THE CURE OF PULMONARY TUBERCULOSIS BY REST AND EXERCISE.** By HUGH M. KINGHORN, M.D. Illustrations Richard G. Badger. Gorham Press, Boston, 1924

In this little book Dr. Kinghorn elaborates in interesting fashion his theories of the more successful method of treating pulmonary tuberculosis. He is well and favorably known as one of the foremost advocates of prolonged rest and of the use of exercise only with utmost caution.

Better to acquaint the reader with the theories underlying the use of rest and to create a favorable background in the reader's mind, the author starts with several chapters devoted to an historical consideration of the subject, giving in some detail interesting features in the lives and viewpoints of Brehmer, Dettweiler and our own Edward L. Trudeau. In the course of these chapters one is brought to realize the transition that occurred from the emphasis laid upon the importance of regulated exercise to that of complete rest. The author "views with alarm" the "Work Therapy" idea as put forth by Dr. Marcus Patterson of Brompton Sanatorium, Frimley, England. He totally disagrees with Dr. Patterson's theory of the beneficence of "Auto-inoculation in Pulmonary Tuberculosis." He contrasts the end results, in from 5 to 9 years, of those patients subjected to Patterson's "Work Therapy," with graduates out the same length of time from Trudeau Sanatorium, Saranac Lake, New York, and with those patients taking the home bed-rest treatment of Dr. Joseph H. Pratt of Boston, much to the advantage of the latter two groups.

Dr. Kinghorn and Dr. Patterson are both a big emphasis in their advocacy of their theories. In the experience of most of the tuberculosis workers in this country, the more practical course has been found to lie in a path somewhat between these two extremes, inclining, perhaps, a trifle more in the direction of Dr. Kinghorn, than of his English conferee.

FOSTER MURRAY

**TWO LECTURES ON GASTRIC AND DUODENAL ULCER, A RECORD OF TEN YEARS' EXPERIENCE.** By SIR BERKELEY MOYNIHAN, Leeds. John Wright & Sons, Ltd., Bristol, England, 1923

In these two lectures the author discusses very thoroughly the subject of gastric and duodenal ulcer, and relates his own experience with 715 cases, over a period of ten years. Of these, there were 531 cases of duodenal ulcer, with not a single operative death since 1912.

This remarkable record can be explained only on the basis of very careful work, thorough study of each individual case, a proper pre-operative preparation of the patient, and the application of the best possible methods in each particular case. The surgeon, he declares, must always be eager in search of a "under judgment, or

better method, and must always give the fullest consideration that increasing experience may seem to teach.

The author has very definite views as to the surgical pathology of ulcer. "I hold," says he, "that a 'chronic ulcer' whether of the stomach or duodenum, is a visible and palpable lesion, which has existed for months or years." There can be no doubt as to what he intends to convey by this statement.

Pain as a diagnostic symptom in ulcer must be of an absolutely characteristic kind. "In the same patient, after the same meals, it appears with the most exact regularity, after the same interval of comfort." Due credit is given to radiology as a diagnostic agent. "In competent hands," he insists, "it is far more accurate than any other method of diagnosis, chemical or clinical, or all other methods combined."

As regards operations. Notwithstanding the fact that gastro-enterostomy was the operation of choice in most cases, he speaks in high terms of Finney's gastro-duodeno pyloroplasty and its modification which is known as Chas. H. Mayo's gastro-duodenostomy, and he concludes with characteristic frankness that "It is more than probable that some of the cases treated a few years ago by gastro-enterostomy, would be dealt with if occurring today, by this method of gastro-duodenostomy with excision of the ulcer or its destruction by the cautery."

HERMAN SHANN

**PRACTICAL LECTURES** Delivered under the Auspices of The Medical Society of the County of Kings, Brooklyn, New York. 1923-1924 Series. Octavo of 484 pages with 132 illustrations and 3 color plates. New York, Paul B. Hoeber, Inc., 1925. Cloth, \$5.50

This book assembles twenty-five unusual lectures given before The Medical Society of the County of Kings (Brooklyn). These are the well known Practical Lectures which, as part of the Brooklyn educational program, have attracted so much attention.

The lectures are not heavy or pedantic but very readable and interesting, and given by famous teachers of medicine in their very best teaching manner.

The book is practical in the sense that the lectures meet the needs and answer the questions of every day medical practice. The specialist as well as the general practitioner will gain much by this easy reading in the broad field of general practice to which, finally, every patient belongs.

Though the blackboard and the patient are missing, the book is almost as good as the lectures which have had such phenomenal success. The illustrations are numerous and excellent and the book itself beautifully done. We are looking ahead to the second volume. It should be a great success.

C. A. G.

**INSANITY AND LAW** A Treatise on Forensic Psychiatry. By H. DOUGLAS SINGER, M.D., M.R.C.P. (London), and WILLIAM O. KROHN, A.M., M.D., Ph.D. P. Blakiston's Sons & Co., Phila., Pa. 1924

It has been a real pleasure to review this book. In fact, the subject was so well presented that we read the book a second time. In spite of its brevity, it fills a great want in forensic psychiatry. The authors will be remembered as the alienists for the prosecution in the recent Loeb-Leopold case. The first half of the book takes up the various mental disorders. The second half is devoted to the legal aspects. The authors are not like so many other recent writers in this field who indulge in speculative theorizing. And while evidently well acquainted with the modern views of certain criminologists, they do not follow their lead in attempting to show that all crime is due to disease. Neither do they regard the question of responsibility as a myth. The book can be well recommended as a sound scientific exposition of the relations of psychiatry to the law.

CANCER NATURE DIAGNOSIS AND CURE By FRANCIS CARTER WOOD M.D. Director Institute for Cancer Research, Columbia University

MAN AND THE MICROBE HOW COMMUNICABLE DISEASES ARE CONTROLLED By C E A WINSLOW, Dr P H, Professor of Public Health, Yale School of Medicine

COMMUNITY HEALTH HOW TO OBTAIN AND PRESERVE IT By D B ARMSTRONG M.D., Sc.D., Executive Officer of the National Health Council

THE BABY'S HEALTH By RICHARD A. BOLT, M.D., Gr.P.H., Director Medical Service, American Child Health Association

PERSONAL HYGIENE THE RULES FOR RIGHT LIVING By ALLAN J McLAUGHLIN, M.D., Surgeon United States Public Health Service. Bound in full flexible fabricoid Price per volume, 30 cents Funk & Wagnalls Company, New York, 1924

This is a series of twenty small volumes averaging about 70 pages each, edited by the National Health Council, and intended for popular distribution. Below are brief comments on the first five of this series

A J McLAUGHLIN and J A TOBEY

*Personal Hygiene*

This volume is filled with good, sound advice in personal hygiene. First describing what good health is, the authors advocate for the reader an appraisal of health—otherwise a complete physical examination. Then follow several chapters on the proper care of the body with the ultimate aim of lengthening the span of life.

D ARMSTRONG

*Community Health*

The author's words on the Prevention of Infectious Diseases are worth recommending to everyone, the work of communicable disease control would be far easier if this were done. In another chapter, he also shows how the non-infectious diseases may be prevented. Dr Armstrong's final plea deserves special comment. 'A community will best attain health that seeks health not merely as an end in itself. We must end sickness and increase health so that each individual may have life and life more abundant, and so that each community may be fit to do its share in the life of the nation'

F C. WOOD

*Cancer*

This is the sanest statement for lay consumption which we have yet seen. Dr Wood writes briefly of the occurrence, the classification and the contributory causes of cancer in the first three chapters. There follows a brief statement regarding experimental study of cancer. He then describes the varieties and symptoms and treatment in subsequent chapters. The chapter on quacks should be published in heavy type on the first page of every newspaper in the country.

C. E. A WINSLOW

*Man and the Microbe*

Winslow has given us in his usual concise style an excellent little treatise on disease prevention. He describes briefly the roles of water, milk food and insects in the spread of diseases, devotes a chapter to the contact infections, and presents a final chapter on artificial control of immunity in which he describes the development of vaccine and serum prophylaxis and therapeutics.

R. A. BOLT

*The Baby's Health*

How anyone can condense so much information in so little space is a mystery until one reads this little essay of Bolt's. It should be given to every mother and every prospective mother in the country.

ALCOHOL AND PROHIBITION IN THEIR RELATION TO CIVILIZATION AND THE ART OF LIVING, by VICTOR G VECKI, M.D., San Francisco, Cal J B Lippincott Co, Philadelphia and London 1923 Price, \$2.00

The author has given us a clear, concise and unprejudiced presentation of the whole question of alcohol. One is struck by the evident fairness of his presentation of the situation. No matter what one's belief may be concerning this subject, he cannot but get a broader viewpoint through reading Dr Vecki's book.

E H M

HEALTH AND DISEASE, THEIR DETERMINING FACTORS, by ROGER I LEE, M.D., Professor of Hygiene in Harvard University, Visiting Physician, Massachusetts General Hospital Little, Brown and Co, Boston, 1923

This book is intended particularly for the laity, and its reading should be encouraged by every physician, for the successful practice of medicine depends so much upon the cooperation of the patient. It is a short-sighted policy to attempt to keep the layman in ignorance concerning matters affecting his health. It has been by education of the public that such vast strides have already been made in the reduction of death rates and yet the practice of medicine has never suffered thereby.

Lee has furnished a text simple in language, understandable by any reasonably intelligent individual, and outlining the principles of individual and community hygiene.

E H M

BASAL METABOLISM Determination of the Metabolic Rate in the Practice of Medicine. By JOHN T KING JR., M.D. Octavo of 118 pages Baltimore, Williams & Wilkins Company, 1924 Cloth, \$2.50

In this volume, the author attempts to survey the literature briefly and to stress the values of the determination of the basal metabolism which appear from its application in the actual practice of medicine. The physiologic factors involved in the test and the clinical deductions to be made from the readings are covered in a manner which, considering the present state of our knowledge of this subject, is quite commendable. Unfortunately, however, scant attention has been given to the actual clinical determination of the basal metabolism. The general underlying principles are well stated but there is a lack of specific detail to guide one in the performance of the test. Such a simple, definite description would be of great value. When one reads about the performance of the test in current periodicals he is told that the method is so simple as to be easily within the range of comprehension of the average high school student, in the twinkling of an eye, however, he is led into a maze of complexities of Einsteinian proportions and he finds that he is assumed to possess a knowledge of certain technical problems unknown to the unintelligentsia. As a matter of fact, the methods can be described in very simple form, and the reviewer cannot help but feel that the author has missed a great opportunity in failing to do so.

HENRY M FEINBLATT

**THE CULTURE OF THE ABDOMEN, THE CURE OF OBESITY AND CONSTIPATION** By F. A. HORNIBROOK Preface by SIR WILLIAM ARBUTHNOT LANE, Bart, C.B., M.S., Consulting Surgeon, Guy's Hospital etc William Wood & Co New York, 1924 Price, \$2.25

This sixty-seven page book has been rather lavishly produced, as regards binding and illustrations, probably because in a preface Sir William Arbuthnot Lane has highly recommended it as an authoritative work on the medical treatment of viceroposis. The author is a physical trainer, not a physician, and has based his conceptions of gastrointestinal physiology on obsolete theories and on Lane's well known obsessions. The greater part of the book is given over to a discussion of these theories and the value of regularity in eating, sleeping and exercise. The "systems of exercise" which are the excuse for the publication of this book and which are supposed to be the invention of the author, are but eight in number and are confined to the last chapter. They appear to be excellent exercises for development of the abdominal wall and thorax, but probably no better than many other systems in common use by other physico-therapists. They are beautifully illustrated. A

**DIABETES, A HANDBOOK FOR PHYSICIANS AND THEIR PATIENTS** By PHILIP HOROWITZ, M.D., with thirty-four text illustrations and two colored plates. Second Edition Revised and Enlarged. Paul B Hoeber, Inc., New York, 1924

This is a concisely written work on this subject showing by case reports the nature of the treatment used in the various types of diabetes and its complications.

Like other books on this subject, it also contains food recipes and a description of the various chemical tests used in the diagnosis and management of the diabetic patient.

It contains many practical points concerning the treatment of this disease and will be found worthy of the attention of medical readers. C E HAMILTON

**THE TREATMENT OF THE COMMON DISORDERS OF DIGESTION, A HANDBOOK FOR PHYSICIANS AND STUDENTS** By JOHN L KANTOR, Ph.D., M.D., Chief Gastrointestinal Diseases, Vanderbilt Clinic. Illustrated. The C V Mosby Co, St Louis, 1924 Price, \$4.75

This is a comprehensive treatise on the therapy of gastro-intestinal disorders. Few pages, good illustrations, well organized information are its characteristics. All detail is concise without "frills." Can be recommended to every physician's library. B M Eis

**PECULIARITIES OF BEHAVIOR, WANDERING MANIA, DIPLOMANIA, CLEPTOMANIA, PYROMANIA AND ALLIED IMPULSIVE ACTS** By WILHELM STEKEL. Authorized English version by James Van Teslaar. Vols 1 and 2. Boni & Liveright, New York. 1924

These two volumes represent quite an ambitious desire on the part of the author to present the value of psychoanalysis in the interpretation of disorders of human conduct. While many of his case studies are extremely interesting many of them are incomplete and it is felt that the deductions are based upon premises not well founded. It is also felt that interpretation symbolically is indulged in freely and often in an unwarranted manner. The author gives one the impression of being over enthusiastic as to the real therapeutic value of psychoanalysis.

The material is presented in a very disjointed manner and as a consequence difficult to review. He endeavors to cover a very large field in a comparatively small space. Although the book is intended for the beginner it is felt that the author gives the impression that psychoanalysis is easier for the patient and the physician than it really is. The beginner who wishes to learn the real principles of psychoanalysis is advised to defer the reading of this work until he has become familiar with some of Freud's better known works. However there is much that is interesting in the volumes but it must be emphasized that the claims of the author are often extravagant. S R. LEAHY

## BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these columns will be made for review as dictated by their merits or in the interest of our readers.

**CLINICAL THERAPEUTICS** By ALFRED MARTINET, M.D., Paris, France. Authorized English Translation from the Second Revised and Enlarged Edition. By LOUIS T D'EM SAJOUS, M.D., Philadelphia. Complete in two royal octavo volumes. Vol. I—Therapeutic Agents and Procedures. Vol. II—Treatment of Symptoms and Diseases. F. A. Davis Company, Publishers. Philadelphia, 1925. Price, \$16.00 net.

**A LABORATORY MANUAL OF PHYSIOLOGICAL CHEMISTRY** By ELBERT W ROCKWOOD, M.D., and PAUL REED ROCKWOOD, M.D. Fifth Edition, revised and enlarged. Illustrated with four colored plates and forty-three text engravings. F. A. Davis Company, Publishers, Philadelphia, 1924. Price, \$4.00 net.

**PSEUDO-APPENDICITIS** A Study of Mechanical Syndromes of the Right Lower Quadrant Simulating Appendicitis. By THIERRY DE MARTEL and EDOUARD ANTOINE. Authorization translation from the French. By JAMES A EVANS, M.D. Illustrated with forty-one engravings. F. A. Davis Company, Publishers, Philadelphia 1925. \$3.00 net.

**FEEDING, DIET AND THE GENERAL CARE OF CHILDREN** A Book for Mothers and Trained Nurses. By ALBERT J BELL, M.D. Second revised edition. Illustrated. F. A. Davis Company, Publishers, Philadelphia, 1924. Price, \$2.00 net.

**AN INTRODUCTION TO DERMATOLOGY** By SIR NORMAN WALKER. Eighth Edition. With ninety plates and eighty illustrations in the text. William Wood and Company, New York, 1925. Price, \$7.00.

**A CONTRIBUTION TO THE STUDY OF PERNICIOUS ANEMIA AND APLASTIC ANEMIA** By ARTHUR SHEARD, M.D. A Thesis presented for the degree of Doctor of Medicine in the University of Leeds, December 1923. William Wood and Company, New York, 1924. Price, \$2.50.

**INTERNATIONAL CLINICS** By Leading Members of the Medical Profession Throughout the World. Volume I. Thirty-fifth Series 1925. J B Lippincott Company, Philadelphia, 1925.

## RESULTS OF INVESTIGATIONS OF CAUSES OF DEATH AT CHILDBIRTH \*

By OTTO R. EICHEL, M.D

ALBANY, N Y

A Further Preliminary Note on Studies Being Made in the Vital Statistics Division,  
New York State Department of Health

IN this paper we shall present some general provisional statistics from studies of puerperal mortality which have been in progress in our office during the past year. I am pleased to acknowledge the help I have received from my Research Assistant, Miss Carolyn A. Bonds, in preparing this paper. I am indebted to her for most of the arduous labor involved in compiling and analyzing the primary data upon which my comment is based. In the brief time at our disposal it will be impossible to do more than merely indicate some of the more interesting features of these data from a descriptive standpoint.

The death rate from causes connected with childbirth has been relatively high in New York State for many years. During the seven years, 1915-1921, the death rate from all puerperal causes combined in the city of Birmingham, England, was below 35 per 10,000 births and stillbirths combined, in New York City during those years it ranged between 44 and 70, and in New York State, outside of New York City, it varied from 53 to 83. There occurred in the entire State of New York during the five years, 1918-1922, exactly 7,000 deaths from all puerperal causes, of which 3,461 were registered in New York City and 3,539 in the rest of the State. Puerperal sepsis comprised 27 per cent of these deaths in the entire State, 25 per cent in New York City, and 30 per cent in the rest of the State.

Although the trend of the death rate from all puerperal causes combined was generally downward from 1910 to 1916 in New York State, it rose sharply in 1917 and reached a high peak in 1918. Since then it has declined, but the mor-

tality has remained at a higher level than during the years 1912-1916. The rate fell from 65.1 in 1910 for the entire State, to 49.1 in 1916, rising sharply to 75.3 in 1918, and dropping to 51.7 in 1923. The death rate from puerperal sepsis declined from 22.3 per 10,000 births and stillbirths combined for the entire State in 1910, to 12.5 in 1923. (Chart I shows the trend of the death rate for New York City and for the State, exclusive of New York City.)

CHART I

There is a very regular seasonal variation in maternal mortality in New York State. The average monthly death rate from all puerperal causes combined is highest in March and then declines gradually to a low point in September, after which it again rises gradually to the highest rate in March. The average March rate during a recent seven-year period, 1914-1920, was 65.5, and the lowest average monthly rate, in September, was 41.2, or about two-thirds the March rate. There is a similar marked seasonal

\* Read at the Annual Meeting of the Medical Society of the State of New York at Rochester, N. Y., April 22, 1924.

variation in the death rate from puerperal septicemia and from all puerperal causes, exclusive of septicemia (see Chart II) This seasonal varia-

CHART II

tion may possibly be attributed to the greater prevalence of respiratory and renal diseases in the colder months, our final analysis may show definitely whether or not this will account for it

The average annual number of live births in the entire State of New York is 238,364 and of stillbirths, 10,110, the average annual number of deaths for mothers from all causes connected with childbirth is 1,364. During the five years, 1916-1920, stillbirths in this State comprised 4.07 per cent of the total births. During the same period the maternal death rate was 54.90 per 10,000 births, including stillbirths, the septicemia rate, 16.44, and that from all other puerperal causes, 38.46. The deaths from puerperal septicemia comprised just 30 per cent of the total deaths from puerperal causes.

During the five years, 1916-1920, the death rate from *all puerperal causes* was 46.72 per 10,000 births and stillbirths combined in New York City, and 65.87 in the rest of the State—nearly 20 points higher in the latter area. Dividing the rest of the State into urban and rural, the rate for places *under* 2,500 population was 58.51, that for cities *over* 2,500, 69.42, and that for villages *over* 2,500, 71.07. In other words, the death rate is lowest in the very *rural* area of the State.

The death rate from puerperal *septicemia* for the entire State for the five years, 1916-1920, was 16.44, for New York City, only 13.58, and for the rest of the State, 20.29. In the rest of the State the rural septicemia rate was 15.58, and for all cities over 2,500 population it was 23.04.

For the entire period of thirteen years, 1910-1922 inclusive, the mortality from all puerperal causes combined was higher for Upstate\* than

for New York City, the same being true for the death rate from septicemia.

Our publication on the geographical distribution of maternal mortality and stillbirths in New York State shows very great differences in the rates of mortality from causes connected with childbirth in the various counties, cities, and villages of the State. This local variation in rates cannot be accounted for by chance alone, nor are there any outstanding conditions which afford a ready explanation. The presence of many non-resident patients in hospitals is not a factor of great importance in most instances and the practise of arbitrarily excluding non-resident deaths from the rates is not warranted. If this were done, then births to non-resident mothers should likewise be excluded to make the adjustment honest. Moreover, various large cities which contain institutions receiving many non-resident patients, have very low rates, e.g., the average death rate from all puerperal causes in Buffalo, Rochester, Syracuse, Utica, Albany, Binghamton, Schenectady, etc., is below 74 while the rate runs as high as 166 in Watertown, Ogdensburg, Plattsburgh, Middletown, Batavia, etc. Likewise, the average mortality from puerperal septicemia is 20 or below in such large cities as Buffalo, Schenectady, Rochester, and over 40 in Little Falls, Middletown, Plattsburgh, Watertown, Ogdensburg, etc.

Of the many factors to be considered in studying these conditions, not the least important is perhaps the fact that the larger cities have more hospitals, skilled nurses and midwives, and more obstetrical specialists, including physicians who limit their practise entirely to their field. Also, in the large cities a high percentage of births occurs in institutions and the average maternity case probably receives better prenatal and postnatal care. A condition which is perhaps inconsistent with this speculation is the low rural rates, especially from septicemia. I think in this instance the non-resident factor is doubtless important, as many critically ill patients are removed from rural districts to city hospitals.

In this connection it is unfortunate that puerperal septicemia is not better reported as a disease. During the three years, 1920-1922, there were registered in the entire State of New York 1,148 deaths from sepsis and only 877 cases. As during this period there were reported in New York City more cases than deaths, it is obvious that failure to report sepsis must be very extensive among Upstate physicians, or else the infection is more promptly or effectively treated in New York City.

As the suspicion might reasonably exist that the septicemia deaths occur chiefly in the practise of a relatively few physicians and midwives, an attempt was made to determine the facts. Hence we analyzed the distribution of sepsis deaths in the cities to ascertain their prevalence.

\*The terms "Upstate" and "Rest of State" are synonymous.

in the practise of individual physicians. The result showed that they were not at all limited significantly to the practice of any one or any group of physicians in any city, indeed, they were more or less uniformly distributed among many physicians, including men of high reputation as to character and skill. In the city of Troy, during a recent five-year period, there occurred 26 septicemia deaths in the practice of 21 physicians, only one man having as many as three.

Perhaps the commonest explanation offered of our high maternal death rate is that midwives are chiefly to blame. The truth of this also was susceptible of rather close determination, by making direct inquiries of the physicians who registered puerperal deaths during the twelve months preceding July 1, 1923. There were recorded Upstate 687 deaths from causes connected with childbirth, replies to our inquiries, satisfactory for analysis, were received from physicians for 485, or 71 per cent of these deaths. In these replies we are confronted by the bald fact that only 18, or 3.7 per cent, of the patients had been under the care of a midwife at some period before a physician was called. This in itself shows at once that the midwife is by no means the important factor she is accused of being. It must also be remembered that the term "midwife" can be loosely used. The same careful distinction should be drawn between the irregular unlicensed "midwife" and the bona fide trained woman, licensed by the State to practice midwifery on the basis of her qualifications, as between the regular physician with an "M.D." degree and the chiropractor and other irregular practitioner. The professional midwife should not be blamed for the misdeeds of alleged midwives.

Careful reading of the physicians' reports on these 18 patients previously attended by midwives shows that 7 of them died of *septicemia* and 11 from other puerperal causes. These reports fail to show how many of the so-called midwives were licensed or qualified to practice midwifery. Of these 11 deaths there were only two in which it seemed definitely clear that the midwife may have been to blame, viz., deaths from hemorrhage due to placenta previa. Of the remaining 9 cases, one died of tuberculosis—the physician believed overwork and her large family were contributory causes and fails to blame the midwife. Another died of nephritis and profound anemia, although she had been attended by a midwife, the doctor's description of her general health shows it was so poor for two years preceding that pregnancy itself was inadvisable and dangerous, he exonerates the midwife by saying "her death was indirectly self-induced." Three other died of eclampsia, one complicated with broncho-pneumonia and one with acute nephritis. All three are blamed

on lack of prenatal care, for which, obviously, the midwife is not responsible. In another case, the patient died suddenly from pulmonary embolism following difficult labor, and the physician believes there was only a "very faint possibility of saving her had she been delivered earlier," and, therefore, does not seem to blame the midwife. Another died from postpartum hemorrhage, which the physician states was not recognized early enough, although he also states that he was called by the midwife. One patient, very anæmic, died from rupture of the uterus, the physician believing she might have been saved if a Caesarian section had been performed, it appears that he was called by the midwife when the patient's serious condition was discovered, hence she probably was not to blame and certainly not for the abnormal condition which existed. Another patient died following Caesarian section done for malposition and some very obscure obstacle to delivery, which three physicians were unable to positively diagnose. Detailed history of the case shows the midwife called a physician after the patient had been in labor about 12 hours—she had given birth to 12 children with no great difficulty. The physicians, themselves, attempted version, forceps, etc., without success, eventually delivering a child which died soon afterward. The report states it is possible that the patient might have been saved if a physician had been called earlier, but their clear history of the case shows her condition was extremely grave from the beginning. Finally, there are two cases in which it is highly probable that the midwives, both licensed, may have been at fault, both patients died from hemorrhage due to placenta previa and in both instances it seems probable that the seriousness of the condition was not recognized early enough or the physicians not called soon enough. Therefore, out of the entire 11 deaths from causes other than sepsis in which midwives, licensed or otherwise, preceded the physician, there are only two, or less than one-half of one per cent of the total classified deaths, in which the midwives' responsibility can be assumed with reasonable certainty.

During the 12 months preceding last July 1, 1923, 205 deaths from puerperal sepsis were registered in Upstate New York (this cause being given alone or associated with other causes). Inquiries sent to the reporting physicians resulted in 138 replies satisfactory for tabulation, or 67 per cent of the total 205 deaths. As we have just noted, only seven cases had a midwife in attendance before a physician was called. In only two of these does the physician directly blame the alleged midwife and in one, some other physician was in attendance after the midwife delivered the woman, in the other the criminal abortion was performed by an alleged midwife in New Jersey. Of the other five sepsis cases, in one the physician states the infection

variation in the death rate from puerperal septicemia and from all puerperal causes, exclusive of septicemia (see Chart II) This seasonal varia-

CHART II

tion may possibly be attributed to the greater prevalence of respiratory and renal diseases in the colder months, our final analysis may show definitely whether or not this will account for it

The average annual number of live births in the entire State of New York is 238,364 and of stillbirths, 10,110, the average annual number of deaths for mothers from all causes connected with childbirth is 1,364. During the five years, 1916-1920, stillbirths in this State comprised 4.07 per cent of the total births. During the same period the maternal death rate was 54.90 per 10,000 births, including stillbirths, the septicemia rate, 16.44, and that from all other puerperal causes, 38.46. The deaths from puerperal septicemia comprised just 30 per cent of the total deaths from puerperal causes.

During the five years, 1916-1920, the death rate from *all puerperal causes* was 46.72 per 10,000 births and stillbirths combined in New York City, and 65.87 in the rest of the State—nearly 20 points higher in the latter area. Dividing the rest of the State into urban and rural, the rate for places *under* 2,500 population was 58.51, that for cities *over* 2,500, 69.42, and that for villages *over* 2,500, 71.07. In other words, the death rate is lowest in the very *rural* area of the State.

The death rate from puerperal *septicemia* for the entire State for the five years, 1916-1920, was 16.44, for New York City, only 13.58, and for the rest of the State, 20.29. In the rest of the State the rural septicemia rate was 15.58, and for all cities *over* 2,500 population it was 23.04.

For the entire period of thirteen years, 1910-1922 inclusive, the mortality from all puerperal causes combined was higher for Upstate\* than

for New York City, the same being true for the death rate from septicemia.

Our publication on the geographical distribution of maternal mortality and stillbirths in New York State shows very great differences in the rates of mortality from causes connected with childbirth in the various counties, cities, and villages of the State. This local variation in rates cannot be accounted for by chance alone, nor are there any outstanding conditions which afford a ready explanation. The presence of many non-resident patients in hospitals is not a factor of great importance in most instances and the practice of arbitrarily excluding non-resident deaths from the rates is not warranted. If this were done, then births to non-resident mothers should likewise be excluded to make the adjustment honest. Moreover, various large cities which contain institutions receiving many non-resident patients, have very low rates, e.g., the average death rate from all puerperal causes in Buffalo, Rochester, Syracuse, Utica, Albany, Binghamton, Schenectady, etc., is below 74 while the rate runs as high as 166 in Watertown, Ogdensburg, Plattsburgh, Middletown, Batavia, etc. Likewise, the average mortality from puerperal septicemia is 20 or below in such large cities as Buffalo, Schenectady, Rochester, and over 40 in Little Falls, Middletown, Plattsburgh, Watertown, Ogdensburg, etc.

Of the many factors to be considered in studying these conditions, not the least important is perhaps the fact that the larger cities have more hospitals, skilled nurses and midwives, and more obstetrical specialists, including physicians who limit their practice entirely to their field. Also, in the large cities a high percentage of births occurs in institutions and the average maternity case probably receives better prenatal and postnatal care. A condition which is perhaps inconsistent with this speculation is the low rural rates, especially from septicemia. I think in this instance the non-resident factor is doubtless important, as many critically ill patients are removed from rural districts to city hospitals.

In this connection it is unfortunate that puerperal septicemia is not better reported as a disease. During the three years, 1920-1922, there were registered in the entire State of New York 1,148 deaths from sepsis and only 877 cases. As during this period there were reported in New York City more cases than deaths, it is obvious that failure to report sepsis must be very extensive among Upstate physicians, or else the infection is more promptly or effectively treated in New York City.

As the suspicion might reasonably exist that the septicemia deaths occur chiefly in the practice of a relatively few physicians and midwives, an attempt was made to determine the facts. Hence we analyzed the distribution of sepsis deaths in the cities to ascertain their prevalence

\*The terms "Upstate" and "Rest of State" are synonymous.

premature birth, whether criminal or otherwise.

As to diseases associated with important puerperal causes of death, it may be of interest to mention that out of 2,933 puerperal deaths we are studying, there were 1,347, or about one-half, in which the death was attributed by the physician to a single cause, and 1,337, or almost an equal number, in which the cause of death was associated with one contributory condition, either puerperal or other illness. There were only 243 deaths in which the primary cause of death was associated with two contributory causes. For example, out of 2,933 deaths the primary cause in 670, or 23 per cent, was due to toxemia of pregnancy, this toxemia of pregnancy occurred without any contributory cause in 420 cases, or 63 per cent of all the toxemias, 215, or 32 per cent of the toxemias had one contributory cause, and 33 cases had two contributory causes. Of the total 2,933 puerperal deaths, 370, or 13 per cent, were caused by abortion, miscarriage, and premature labor, including criminal and self-induced abortions. Ectopic gestation was the primary cause of death in 100 cases, or 3 per cent of the total. Acute and chronic infectious disease, such as typhoid, influenza, pneumonia, tuberculosis, etc., were the primary causes of death in 369, or 13 per cent of the cases. Puerperal hemorrhage, including placenta previa, was the primary cause of death in 240, or 8 per cent of the cases. Puerperal infection was the primary cause in 346, or 12 per cent of the cases. Our final results will, of course, show all the causes in detail and also associated with other contributory causes.

In order to discover, if possible, some of the basic conditions under which the deaths from puerperal causes occur in this State, certain questions were submitted, during a period of twelve months preceding last July 1, 1923, to each physician who reported a death from any cause connected with childbirth. Inquiries were made concerning 687 puerperal deaths and replies suitable for tabulation were received for 485 cases, or 71 per cent. Of the 485 deaths, 58 per cent occurred in hospitals. Puerperal sepsis as a cause of death in these cases has already been described in detail above, likewise the factor of the midwife. Other facts of importance found were that 30 per cent of the sepsis deaths were reported by physicians as having been *previously under the care of some other physician*, and only 2 per cent under the care of the same physician until death occurred. Of the 485 deaths, 72 per cent were reported as having had a trained nurse or other competent attendant during the puerperium, and 28 per cent were attended by friends, members of the family, neighbors, etc. Hospital care was advised by the physicians in 69 per cent of the cases and was not advised in 22 per cent, 4 per cent of the patients were unable to go to hospitals as they were too ill to go, or

hospitals were too far distant. Of those who were not advised to go, many were believed by physicians to be dying or too ill to be moved any distance. Of those who were advised to enter hospitals, 75 per cent consented and 17 per cent refused, 7 per cent of the patients consented to go to the hospital only after their condition became extremely serious. The reporting physicians stated they believed that the patients had received adequate medical care before confinement in 54 per cent of the cases, that they had not received adequate care in 37 per cent, and that the type of care was unknown for 9 per cent. Of those who had not received adequate medical care before confinement, the physician stated in many instances that it was due to ignorance, neglect, or poverty. Only 2 per cent of the patients refused consultation when it was advised by the attendant. In 9 per cent of the cases, the physician did not advise consultation—possibly because competent advice was not available or the patient was already dying when the physician was called. Obstetricians were available for consultation in the communities of 77 per cent of the decedents, were not available in only 12 per cent, and for only 3 per cent of the cases did the physicians report that obstetricians were many miles distant. This would indicate that for not less than one case out of ten there was no obstetrician available for consultation.

Obstetrical operations, such as version, Caesarian section, high and low forceps, traction, craniotomy, laparotomy, etc., were performed in just 50 per cent of the cases. *The physicians reported that in 42 per cent of the entire 485 puerperal deaths the patient had been previously suffering from an illness which endangered her life when she became pregnant.* Many of these illnesses were such chronic conditions as tuberculosis, heart disease, etc. In only 35 per cent of the cases did the physicians report that there were circumstances or conditions under which the patient's life might have been saved, and in 25 per cent that there were no conditions under which the patient could have been saved. In the remaining cases, on this point the physicians were doubtful or uncertain.

#### CONCLUSIONS

It is a fact, shown by our inquiries and well known to all physicians, that some patients, in spite of the most thorough and competent medical care from the time of conception, and under the most favorable circumstances, will develop abnormal puerperal conditions resulting in death, and that even fatal septic infection will occur from no cause which the physician can determine. The prevention of death in the remainder of the cases would seem to depend upon the following:

- 1 Education of the public as to the necessity for competent medical prenatal care, and as to

resulted from a previous pelvic disease and that the patient had adequate care preceding and during confinement, in another, the physician exonerates the midwife and states he "knows of no circumstances under which the patient might have been saved" In the remaining three cases, the midwife is not blamed and either the patients were seriously ill before she was called, other physicians followed the midwife, or for other reasons she can be absolved from suspicion.

Hence, to sum up, out of the total 18 cases in which the midwives were involved, critical examination of the physicians' own reports reveal that in only 4 cases, or less than 1 per cent, were they able to definitely implicate the midwife. In addition, in most of the 18 cases the question must be raised as to whether or not the so-called midwife who preceded the physicians was a bona fide licensed midwife or an irregular practitioner. Without elaborating further on the question I think these facts obtained from the Upstate medical profession may be accepted as showing definitely that the midwife is an almost negligible factor in the causation of puerperal mortality. This conclusion is consistent with many facts and conditions which there is insufficient time at our disposal to discuss.

An interesting and striking fact disclosed by our preliminary data is that where the fetus has developed to the fifth month or over of utero-gestation, the fetal mortality is 53 per cent among those born to mothers who died from causes connected with childbirth. Out of 1,885 deaths of mothers from maternal causes for which a corresponding birth was reported, 617 of the infants were stillborn and 1,268 live born. Of the live born, 374 died before they completed the first year of life, thus the mortality of the children born to these 1,885 mothers was 991, or 53 per cent. But, during this period there were, in addition to these 1,885 deaths, 1,048 other deaths of mothers in childbirth for whom no birth certificates were found. As the reasons for not finding them in many or most cases were that no child was born or that the fetus was under five months utero-gestation, it is plain that the fetal mortality is very much higher than 53 per cent.

The notes we have already published show that in Upstate New York the death rate of women from all puerperal causes, from puerperal septicemia, and from all other puerperal causes, in each five-year age group at from 15 to 50 years, in proportion to every 10,000 confinements of mothers of corresponding age groups, shows a striking regularity of increase at each successive age from 20 to 50 years, with a rate at the age 15 to 19 slightly above that at 20 to 24. The rate of stillbirths by ages of the mothers shows the same regular distribution upward (see Chart III). When the mortality among married

CHART III

mothers is shown separately, the general distribution is similar, viz, the death rate increasing with the ages of the mothers.

The death rate from all puerperal causes combined in proportion to 10,000 births and stillbirths increases steadily according to the number of children the mother has had. The mortality shows a high point for primiparae—being 606 per 10,000, for mothers who have had from two to seven children the mortality varies between 38 and 45, for each child the mother has beyond seven the mortality increases, reaching the very high point of 1556 per 10,000 for mothers who have had 14 children. The curve showing the distribution of these death rates resembles that of mortality of mothers by their ages described above. These data seem to be highly significant as showing that the risk of death to the mother increases with each child born beyond the number of seven. In fact, the rate shows a slight increase for each child born beyond the number of two, but rises rapidly after the seventh child is born.

Our data on the frequency of maternal mortality, according to the nativity of mothers, shows the mortality is higher among the native born white mothers than among the foreign born white. Of the foreign born, it is higher among Germans, Canadians, and Scandinavians, and lowest among the Russians (including Russian Hebrews), and next lowest among Austrians, Hungarians and Poles. The mortality among the colored is very high—nearly twice as high as the native white.

Our preliminary data indicate the frequency of abortion, miscarriage, and premature birth, including criminal and self-induced abortion, as the cause of puerperal sepsis. Out of 477 sepsis deaths which we are studying, 299, or 62.7 per cent, were from these causes. Criminal and self-induced abortion preceded septic infection in 82, or 17.2 per cent of the total 477 deaths, in other words, a little less than one-fifth of the septicemia deaths followed criminal interference, and over one-half followed abortion, miscarriage, or

Janet sums it all up as a weakening of the faculty of psychological synthesis

Moeibus says it is a state in which ideas, many fanciful, control the functions of the body

Strumpell declines to give a definition, but describes the condition by various examples, and summarizes the symptoms

Stevens says hysteria is a functional disease of the nervous system, manifested by symptoms of the most varied character, and associated with impaired will-power and increased impressionability

There are a good many other attempts to define hysteria, and it seems to the author that the average student becomes more and more involved in a muddle of perplexities. What seems to be the simplest definition, is that hysteria is a functional mental disease in which the field of consciousness is contracted, and the sub-conscious overshadows the conscious mind. The cause is a psychic trauma. It is much like a dream-state or a hypnoidal condition. The strongest outstanding feature is trouble of the will

*Etiology*—This disease has its origin from some shock to the nervous system. As individuals differ in their powers to withstand various physical hardships, so the mental resistances of people are not alike. Again as in a physical disorder, one with brittle bones is more liable to fracture, and the more likelihood depends on the greater friability of the osseous tissue, so in all the psychotic breakdown, the fibre of an individual nervous system foretells the ability to combat a particular misdirected psychic force. Whether an arm or a leg breaks, or whether the fracture is serrated stellate or simple in its division lines of the bone, also depends on the force of the power causing the trauma, and the quality of the bony texture. Thus, one may get analogous psychic disturbances of degree and kind, depending upon the amount of psychic shock and individual differences of resistance to such shocks.

There seems to be no age exempt from hysteria, although most cases occur when the psychosexual fantasies are on the most active ascendant as in the late puberty. In the writers experience, both sexes are about equally attacked. There seems to be little difference whether education or so-called culture is present, although farm hands seem to be the least affected, and school-teachers the most. The largest group fall into that class of people who have the greatest difficulty to make financial ends meet, so that they can live as their more intimate friends and relatives do.

More cases are seen when temperature extremes are present, as in the hottest summer and coldest winter days. One attack seems to predispose to others, and succeeding attacks develop more often in proportion to the number and severity of the previous ones.

Heredity plays quite a part and frequent cases are seen in the same families. Close affiliations with hysterical patients often predispose to the disease. A long-continued unpleasant mental strain at times needs only a comparatively minor psychic trauma to produce a major hysteria. This mental strain may be loss of a friend, sickness, financial reverses, unpleasant environment, an accident which may have happened to the patient or to another person, a disrupted love affair, etc., embracing every human process of reasoning and endeavor. The onset is usually acute.

*Symptoms*—These are of two different kinds: first, the stigmata or those symptoms which predominate in whole or in part, all hysterics, and then the others which vary with the cases. The most prominent stigmata are areas of anesthesia, anesthetic palate, anesthetic cornea, contracted visual field, hypersuggestibility, alterations of acts and person, fugues and flights, troubles of the will and habit, spasms and tics.

Among the second type of symptoms may be mentioned absentmindedness, feelings of incompleteness, need of attracting attention, transfers and equivalences of thoughts and acts, paralyses, contractures, absence or distortions of the special senses, dreams and nightmares, variations in the moods without apparent causes, and so-called tantrums. As in other diseases, when the patient recovers, all the symptoms disappear.

*Anesthesia*—The patient is often unaware of this symptom until the examiner points it out to him. The skin anesthesia is not distributed along any particular nerve course, but occurs in patches of varying size, at times taking in a whole extremity, and often stops at a definite line of demarcation. This has given rise to the term "stocking anesthesia" in the leg, or "glove anesthesia" when it occurs in the hand or forearm. There are no sensory nerves which have such a definite line of demarcation. It is not uncommon to see one-half of the whole body anesthetic, from the vertex of the head to the sole of the foot, while the other half of the body is perfectly normal. Such a condition must obviously be without anatomical foundation. The test may be made by pricking the patient with a needle and asking whether it is felt or not. A more discriminating way is to test out all the sensibilities, as heat and cold, with test tubes containing water of widely different temperatures, the touch sense, by lightly stroking the part with a fine hair or a small piece of cotton, and the pain sense by using the needle pricks before mentioned. For a hasty examination the needle gives sufficient data.

The cause of this symptom is entirely a functional affair, and in no way has to do with an abnormality of the sensory nerve endings. In fact in many cases the location of the anesthesia may vary from day to day. At times a casual suggestion is enough to indicate to a patient that

the very grave dangers of criminal or self-induced abortion

2 Education of the public as to the undesirability of confinement of the mother by any one except a person licensed to practice obstetrics or midwifery

3 Suppression of the criminal abortionist

4 Immediate and competent care of the patient suffering from spontaneous or accidental abortion

5 Education of the public as to the need for prompt medical care of any abdominal condition connected with pregnancy, or any other illness occurring during pregnancy

6 Adequate clinical and hospital facilities for the care of the poor and those of moderate means

7 Measures to make available, if possible, expert obstetrical advice for physicians in remote rural districts, or facilities for early removal of abnormal cases to the obstetrical expert

8 Elevation of the standards of obstetrical training and practice for physicians

N B—This conclusion is warranted by the reports of the physicians themselves on puerperal deaths, which show that in many cases delay or lack of skill on the part of the first physician called seriously endangered the patient's life or actually began the chain of events ending in her death

9 Extreme aseptic precautions in the care of the patient, especially during and after delivery, and particularly if the patient is suffering from a serious illness not connected with the puerperal condition

10 Clinical, pathological, and statistical research to discover facts at present unknown, and to determine the routes of puerperal infection

Finally, in conclusion, it may be added that it would be wrong to convey the impression to the public that pregnancy in itself is a dangerous condition. On the contrary, during a recent five-year period in New York State there were 1,242,374 live births and stillbirths combined, and 6,821 deaths from causes connected with childbirth, therefore, only one-half of one per cent of the mothers died

## HYSTERIA \*

### An Epitome

By SIEGFRIED BLOCK, A.M., M.D., F.A.C.P.,

BROOKLYN, N. Y.

THE uncertainty with which the diagnosis of hysteria is made by so many practitioners, together with the varied descriptions given in text books covering this subject, have suggested a short paper which shall include only the essentials of this functional psychoneurosis. It may not be amiss to give a few of the standard college book definitions, chosen at random, to get an idea how authorities vary in their elucidation of this subject.

Osler calls it a disorder in which the emotional states control the body, leading to perversion of the mental, sensory, motor and secretory functions.

Charcot says it is a psychosis in which morbid states are induced by ideas. The patient is hypersuggestible. The disturbance is in the personality in which the emotions influence the sensory, motor and secretory functions.

Babinski calls it a mental condition due to hypersuggestibility of certain sensory, motor and secretory functions, with a superimposed group of symptoms as muscular atrophy. The superimposed symptoms cannot be induced by suggestion.

Freud and Breuer follow the ancient Greek idea of a sexual base (hence the name). They

teach that before puberty often on a constitutional base there develop a group of sexual activities which are usually perverse and in the psychic sphere. There gradually grow out of this a series of fantasies which are suppressed, and a conflict between the repressions and normal libido gives rise to certain manifestations, which is termed hysteria. Thus, Freud's theory is based on sexual traumata in early childhood.

Starr claims there is a permanent functional mental condition which he calls the hysterical temperament, and certain temporary attacks of mental or emotional disturbance. The characteristics of the hysterical temperament are an abnormal sensitiveness to impressions and sensations, a susceptibility to suggestion, an unusual desire for attention and notice, variations of the moods not due to apparent causes, lack of judgment, and an incapacity to exercise control over thought, a tendency to act on sudden impulses, a foolish wilfulness, moral obliquity, and frivolous fancies.

Aschaffenburg, of Cologne, says the whole thing is a false relation between stimulation and reactions, and a tendency to convert these reactions into physical manifestations—this is especially true in the emotional sphere.

\* Read at the Annual Meeting of the Sullivan County Medical Society at Liberty, N. Y., October 10, 1923.

tastes are not so impossible as those of the casual dreamer. The hysterical dream also occurs more frequently and repeats itself either exactly or symbolistically at intervals.

The waking reaction to a dream, in those afflicted with hysteria, is very different from a normal healthy individual. The feeling of joy and sorrow, like and dislike, are often based upon a somnambulistic experience which the waking individual does not remember. That is, the person reacts to the dreams in his everyday life, but it is possible that the dream experience is forgotten and the individual cannot explain why he or she behaves in a particular way. On careful study of these hysterics as mentioned above, it is not difficult to realize that they do not really come out of this dream-state. They are, so to say, in a subconscious state when they should be wide awake, and fully alert to all those sensations, thoughts, stimuli, etc., which control active psychic life. Failing, they act only partially as one would expect they should, and the result is not only an inefficiency due to inability, but often a perverted action, an action uncontrolled by the proper associations, and through dissociations, as in dreams, unnatural thoughts and actions are produced.

*Fugues and Flights*—This is a peculiarity which is not uncommon in the hysterics. As a somnambulist walks in his sleep, and does things which in his waking state he will not do, so the hysteric, during an attack may wander away from home. He may not be able to recall his name or know how he reached the place where he was found, and he may be surprised when he is told that he is not normal and that his actions are peculiar. At a future time when the attack has passed over, he will not be able to remember how or why he wandered away. There are cases in which a perfectly lovely wife or devoted husband will go off with another partner, and on coming out of the hysterical trance regret the act and will be bitter against the second mate for assisting in the escapade. The psychology of such an act is described in various ways by different observers. Some claim that in most of the cases, as in a dream, a wish is fulfilled. That is, the hysterical patient had wished to run off with another, but his best judgment told him not to do it, yet he throws aside this sound reasoning and gives himself a sort of "mental knock-out blow." He is now unhampered by either experience or other mental restrictions. A subconscious feeling of "what do I care what happens? I am at liberty to do and act any way I please!"

*Alterations of Personality*—It is almost unbelievable how the hysterical patient at times may engage in a wild fugue. He may travel miles and deport himself in a manner so normal that no one's attention will be attracted to any misconduct. During this period, such an individual

may engage in a healthy conversation, often being able to argue on many points of interest to the people present. He frequently assumes not only different names, but also personalities not his own. The quiet, reserved person may become a bon-vivant, hilarious and light-spirited. Even a miser may become a free spender, and shyness may give way to boldness and impertinence. This all goes on when the subconscious supersedes the conscious level of thought.

It is with great difficulty that the subconscious activities can be grasped by the patient after he is again back to his normal or average self. However, if this subconscious state is again induced, either in a dream or in a hypnotic trance, the patient will react and speak freely, like in the afore-mentioned episodes. If one is in this trance or a dream or hypnosis, and can be made to talk freely about the subconscious fugue, it is often possible to bring out the reason for the peculiar activity, and one step toward a permanent relief of the state has been achieved.

It is very important that during such an examination, the examiner keep his mental poise, and not permit himself to be influenced by the patient's feeling-state. It is only in this way that one is able to properly to form conclusions and discover the reasoning defect.

*Tics and Paralyzes*—It is easy to understand how these patients may have symptoms involving any group of sensory or motor nerves. Sudden blindness, deafness or other sensory disturbance, equal on both sides of the body, following a psychic trauma, is by no means uncommon. Following a fright, a sudden paralysis of an extremity with normal reflexes is by no means rare. In these cases all tests except those of the disease in question are negative. A tic or spasm following or accompanying a psychic disturbance which may be brought about by a physical or mental strain, or sudden shock may be the only symptom of hysteria. In these cases, as in the paralysis above mentioned, the examination is negative, except for this particular symptom.

*Variations in Moods and Tantrums*—The variability of moods, without apparent cause, or night tantrums, both of which may be subconscious overpowering of the conscious mind, are frequently the outstanding feature of such patients. Thus, delusions and hallucinations may be a wish-fulfilling expression of the subconscious hysterical manifestation, which has long been held in abeyance by a conscious restraint. It is really a feeling of "the wildest dreams come true."

*Case Examples*—Fugue. Several years ago, a doctor sent the author L. R., with the following history, and with a diagnosis of hysteria. The man was 48 years of age, a printer, married, three children. Past history negative. He had always been devoted to his family, and worked steadily

he or she will be anesthetic at a certain point

*Anesthetic Palate*—The anesthesia of the palate is the second stigmata in frequency and importance. By having the patient open the mouth and touching the pharynx or the faucial pillars, no gagging reflex is noted. It is usually necessary to hold the tongue down with a suitable depressor to see the reflex action. In healthy individuals this is a very active and delicate reflex test. It is practically never unilateral, and when it occurs without a history of injury to the head or other bulbar symptoms, hysteria must be kept in mind. Many of these patients claim to feel a sort of ball in the throat when they feel ill. This is termed the "Globus Hystericus" and is usually a psychic disturbance, but has nothing to do with the palatal anesthesia. There is no anatomical accounting for this phenomenon. There is neither spasm nor swelling in the pharynx or larynx when this "Globus" is felt.

*Anesthetic Cornea*—As the palate is anesthetic one is often able to elicit a cornea which is minus sensation to the touch of a blunt instrument. Mere conjunctival anesthesia is not as delicate as corneal. A simple way to investigate this point is to ask the patient to look far upward and with the pencil to touch the edge of the iris where it joins the sclera. If one touches the cornea in front of the pupil, the sight of the foreign body makes the eye wink and this is a useless procedure.

*Contracted Visual Field*—This test is of value in confirmation of a suspected diagnosis of hysteria. Either an ordinary perimeter as used by ophthalmologists may be employed to map out the field of vision, or more crude methods will suffice. In most of the cases all that is necessary is to have the patient look straight in front and then with an object in one hand, the examiner slowly moves it in all directions. The patient is asked to tell when the object becomes invisible as it is moved gradually further from the axis of vision. The proper allowance should be made for ocular disturbances, such as astigmatism, etc. When the perimeter is at hand the color fields may be mapped out. In hysterical fields the color outlines are different from normal. In healthy persons, red can be seen over the widest area, while in the hysterics any other color is liable to take the place of red. No diagnosis should be made on this stigmata alone, but a combination of several stigmata with a proper history and the exclusion of organic disease is necessary.

*Hypersuggestibility*—These patients are more suggestible than any others who are not feeble-minded. They are always ready to receive ideas of what to do. This is especially true in matters concerning their personality. Often a mere word as saying an arm is weak or a particular hand is anesthetic, is enough to make it so. Of course this symptom varies in degree with the cases and

there are occasional hysterics who are not hypersuggestible. Hypnotism, which is a stronger suggestive phenomenon, is usually easy with these patients. On careful analysis, it is very difficult to differentiate the hypnotic state from the hysterical state of mind. Both of these conditions are much like a dream-state in which the subconscious realm overpowers the waking consciousness. It is a state of disassociation. It is this disassociation which describes the result of the narrowing fields of consciousness. It is a psychic clouding, so that the "feeling state" of the patient is not clear cut. Although he may be able to think very co-ordinately on those things not affecting his sentimental, spiritual, libidous and other psychic matters pertaining to himself, he is in a mental state of bankruptcy on the latter.

*Alternating of the Personality*—A peculiarity of hysterical patients is that in many cases during an attack they assume an attitude as if they were another individual. They have a sort of double personality. It may be described much like a nightmare. When awake, as a rule, the somnabulist does not know of his night walking, talking or other activity. He is surprised when he is informed of the things he does or says in his sleep. The hysterical patient is in the same way perplexed when his abnormal doings are explained.

Neurologists frequently see patients who have an entirely different self. The genteel girl becomes a boisterous, uncouth individual. The good man may become a criminal. The so-called wish-complex is often thought to play a part in this mental manoeuvre. That is when the patient does not hold back his activities, as in the waking state he is free to carry on a self-transposition and assume an individualistic characterization of what he, in his fondest and freest moments would wish to appear. He acts not what he really is, but how he wants the outside world to think he is. This idea is usually under control of the highest intellectual sphere, but when one is asleep and dreaming, the highest centres are overpowered by the subconsciousness and the person responds to an unmolested mind which in no way is hindered from acting as a child's, unhampered by convention or public opinion. Just as in the dream-state, so in the hysterical condition the patient is a free agent and the most preposterous disassociating mental activities play havoc. It is thus that daydreams materialize and night-terrors take on a real waking actuality.

*Dreams*—Thus it is, the more parallelisms that are drawn with the dream, the more is one inclined to think that a dream corresponds to a hysterical manifestation. Hysterical persons dream, as a rule, more than the average sleeper. Their dreams are more materialistic, and the fan-

tastes are not so impossible as those of the casual dreamer. The hysterical dream also occurs more frequently and repeats itself either exactly or symbolistically at intervals.

The waking reaction to a dream, in those afflicted with hysteria, is very different from a normal healthy individual. The feeling of joy and sorrow, like and dislike, are often based upon a somnambulistic experience which the waking individual does not remember. That is, the person reacts to the dreams in his everyday life, but it is possible that the dream experience is forgotten and the individual cannot explain why he or she behaves in a particular way. On careful study of these hysterics as mentioned above, it is not difficult to realize that they do not fully come out of this dream-state. They are, so to say, in a subconscious state when they should be wide awake, and fully alert to all those sensations, thoughts, stimuli, etc., which control active psychic life. Failing, they act only partially as one would expect they should, and the result is not only an inefficiency due to inability, but often a perverted action, an action uncontrolled by the proper associations, and through dissociations, as in dreams, unnatural thoughts and actions are produced.

*Fugues and Flights*—This is a peculiarity which is not uncommon in the hysterics. As a somnambulist walks in his sleep, and does things which in his waking state he will not do, so the hysteric, during an attack may wander away from home. He may not be able to recall his name or know how he reached the place where he was found, and he may be surprised when he is told that he is not normal and that his actions are peculiar. At a future time when the attack has passed over, he will not be able to remember how or why he wandered away. There are cases in which a perfectly lovely wife or devoted husband will go off with another partner, and on coming out of the hysterical trance regret the act and will be bitter against the second mate for assisting in the escapade. The psychology of such an act is described in various ways by different observers. Some claim that in most of the cases, as in a dream, a wish is fulfilled. That is, the hysterical patient had wished to run off with another, but his best judgment told him not to do it, yet he throws aside this sound reasoning and gives himself a sort of "mental knock-out blow." He is now unhampered by either experience or other mental restrictions. A subconscious feeling of "what do I care what happens? I am at liberty to do and act any way I please."

*Alterations of Personality*—It is almost unbelievable how the hysterical patient at times may engage in a wild fugue. He may travel miles and deport himself in a manner so normal that no one's attention will be attracted to any misconduct. During this period, such an individual

may engage in a healthy conversation, often being able to argue on many points of interest to the people present. He frequently assumes not only different names, but also personalities not his own. The quiet, reserved person may become a bon-vivant, hilarious and light-spirited. Even a miser may become a free spender, and shyness may give way to boldness and impertinence. This all goes on when the subconscious supersedes the conscious level of thought.

It is with great difficulty that the subconscious activities can be grasped by the patient after he is again back to his normal or average self. However, if this subconscious state is again induced, either in a dream or in a hypnotic trance, the patient will react and speak freely, like in the afore-mentioned episodes. If one is in this trance or a dream or hypnosis, and can be made to talk freely about the subconscious fugue, it is often possible to bring out the reason for the peculiar activity, and one step toward a permanent relief of the state has been achieved.

It is very important that during such an examination, the examiner keep his mental poise, and not permit himself to be influenced by the patient's feeling-state. It is only in this way that one is able to properly to form conclusions and discover the reasoning defect.

*Tics and Paralysis*—It is easy to understand how these patients may have symptoms involving any group of sensory or motor nerves. Sudden blindness, deafness or other sensory disturbance, equal on both sides of the body, following a psychic trauma, is by no means uncommon. Following a fright, a sudden paralysis of an extremity with normal reflexes, is by no means rare. In these cases all tests except those of the disease in question are negative. A tic or spasm following or accompanying a psychic disturbance, which may be brought about by a physical or mental strain, or sudden shock, may be the only symptom of hysteria. In these cases, as in the paralysis above mentioned, the examination is negative, except for this particular symptom.

*Variations in Moods and Tantrums*—The variability of moods, without apparent cause, or night tantrums, both of which may be subconscious overpowering of the conscious mind, are frequently the outstanding feature of such patients. Thus delusions and hallucinations may be a wish-fulfilling expression of the subconscious hysterical manifestation, which has long been held in abeyance by a conscious restraint. It is really a feeling of "the wildest dreams come true."

*Case Examples*—Fugue. Several years ago, a doctor sent the author L. R., with the following history, and with a diagnosis of hysteria. The man was 48 years of age, a printer, married, three children. Past history negative. He had always been devoted to his family, and worked steadily

and provided well for them. The firm that employed him discontinued operations during the war, and he spent several months trying to find another position. On one particular Monday morning, he left his home after telling his wife he was going to apply for some position he saw advertised in the newspaper. He was not heard of again for a year and three months, when his wife received a wire from the Cook County State Hospital in Chicago, stating that he was there ready to go home. When he got back to his home in Philadelphia, he could not recall and could not understand how he ever reached the Chicago hospital, or any reason for his having been there, or why he had a big abdominal scar.

Six months later, I saw the man for the first time, and tried every means to get a hint of his journey. His wife insisted he had only a few cents in his pocket when he left that morning to look for a position.

In the writer's office, in the presence of the patient's family doctor and his wife, the man was hypnotized, and then told the following story. He applied for that position, but it was already filled. He felt despondent. He had heard there was a strike in a big varnish factory in Chicago, and conceived the idea of going there to work as a strike-breaker. Opposite the Market Street Station in Philadelphia, he saw an auction sale going on. He took out his gold watch, brought it to the auctioneer to sell, and with this money paid his fare to Chicago. He secured the position in the varnish factory, and after he worked there two months, he was seized with severe abdominal cramps. He was taken to a local private hospital, where an exploratory laparotomy was done. After he was in this hospital for three weeks, and his funds gave out, they told him he would have to leave.

With his bandages still on, he walked the streets of Chicago, and was advised to apply for admission to the Cook County Hospital. It was late at night, and he sat on the steps of the hospital and fell asleep. In the morning he was taken into the hospital, and after being there a long time, and trying every method, it was impossible for him to say exactly where he came from, or who he was. One year later, he had a dream, in which it was revealed to him who he was and where he came from. He could sleep on longer. He told everybody about himself and his home, but the episode of his whole being and experience in Chicago was a blank.

When he was aroused from the hypnosis, the story was related to him. He would not believe it. And only after hypnotizing him again on different days, and each time assuring him his subconscious thoughts corroborated his previous subconscious expressions, did he gradually begin to believe the possibility of the story.

The authorities in Chicago confirmed the facts.

Two years later the man had a second attack of hysteria, and wandered away again and has not been heard from since.

This man had an anesthetic palate, a bilaterally contracted visual field, his right lower extremity was entirely anesthetic to every sensation. Mentally, he was unemotional, his memory was normal, and physically he was very well developed. All serology, blood morphology, and eye-ground examinations were negative. His blood pressure was 120 systolic and 80 diastolic.

*Case 2*—A girl of 18, the only daughter and twin sister of an only son. She was a stenographer in one of the large insurance companies. She was always a well-behaved girl, and had no history of any illness. Two o'clock one morning, the family doctor telephoned that this girl was in a terrible tantrum, in which she said she saw no use in being good, it didn't pay, and she was going to be like other girls, that nobody could stop her, and she was now announcing to the family that she was going to be immoral and stop at nothing. She was quieted with hyoscine and slept until noon the next day. The family then took her to a seaside resort for two weeks, and brought her back for an examination. The case seemed at an end and she returned to her work on the Monday of the next week. On the following Thursday, she sent a telegram from Philadelphia that she was stopping at a hotel with a young man, and that her dream came true.

When the parents arrived at that hotel, she had already left for Washington. Although the police there were notified, the girl was not found or heard from for eight months, when her twin brother accidentally found her in a cabaret chorus in New York.

She had been traveling under an assumed name, and did not recognize her brother. He had her arrested and the magistrate discharged her in the custody of her parents. She was home two months, when her grandmother died suddenly, and during the funeral service she started to cry, and then realized where and who she really was.

It was not so easy to hypnotize this girl as the previous case, but eventually under hypnosis she recounted her whole escapade, and gave as her reason that she was sick and tired of her work, that she wanted to travel, that she wanted to go on the stage, and she didn't care how she got there. She had just read a book in which another girl did almost what she had done, and she imitated her.

The night when she first had that wild dream, was about this book. The story, when told to her twin brother, made him hysterical, and he became amnesic and aphasic immediately. This condition lasted only about ten days. After he

became well, the brother and sister were so suggestible to each other, that whenever one had a pain or an ache, the other would have the same. This hypersuggestibility increased to such an extent, that if one would laugh, even in another room with the door shut, the other would experience laughter, as if there were a mental telepathic current connecting the two. Whenever one was sick in bed, so was the other. Since three years, the brother is dead, having had acute cardiac dilatation following an attack of rheumatism. The girl had an attack of rheumatism the same time as her brother. At present, her corneae, her palate and the soles of her feet are anesthetic to pin pricks. She talks in her sleep. Outside of this, she is apparently normal, has been married, and has a healthy child.

*Case 3*—An apparently healthy woman of 50 was walking through the street, and as she passed the shadow thrown on the pavement by an electric light, she fell. For a moment she thought the shadow was a hole. Her sister was with her and helped her to her feet. They had to call a taxi-cab to take her home, and although all findings were negative, it is now ten years that the woman is paralyzed in her entire right lower extremity, since the fall. When she sleeps, if the sole of her foot be tickled or pricked with a pin, she moves that leg, but when awake she is a helpless cripple. That leg is anesthetic when she is conscious.

*Case 4*—A child of 5 was in a railroad accident, and his father was killed. Since that event, the child is deaf and dumb. Otological and laryngological examinations are negative. Reflexes are all normal, and there is no evidence of brain injury. The condition has existed one year. Under no stress of pain can the child be forced to make any audible exclamation, except a grunt. Similarly, he shows absolutely no response to loud, shrill noises made right near the ear.

*Case 5*—A little girl of ten had her tonsils removed, and after coming out of the ether, she could not talk, and did not talk for two years, despite all forms of treatment. When this girl was given rhubarb and soda with the suggestion that it was a wonderful medicine from a foreign land, two or three doses brought back her speech. She is now about 17, a stenographer, and apparently very healthy. There are no stigmata of hysteria present in this case at this time. Such cases are frequent.

*Case 6*—The wife of a police commissioner had a set of false teeth made. In the beginning, the plate would drop from her hard palate, and she would use her tongue to push it back in place. After several weeks of discomfort, the

dentist suggested the only way to correct it was to make a complete set of lower teeth, figuring that a new, perfect alignment instead of the few remaining lower teeth, would keep the upper set properly adjusted. She then used the tip of her tongue to push the lower set down, and at the same time, the middle or back of her tongue to keep the top set up. This continued for months. Plate after plate of different materials, rubber, platinum, silver, gold, were tried, but gave no relief. This tic had become so firmly established, that even complete removal of the plates did not stop the movements. Osteopathic, chiropractic, Christian Science, psycho-analytic treatments, suggestive operations, fantastic medicines, changes of climate, all gave no relief. Her maseters became enormously developed from constant use. The tic increased to the jaws and neck muscles to such an extent that it interfered with her swallowing. The woman became so bad that she could not eat, and died of starvation.

*Case 8*—To illustrate a type of hysteria which affects the mental condition, without any physical manifestations at all. A girl, 19, was in love with a married man of 35, and as time passed her affection increased. The man was always dutiful to his family, never neglected his wife nor showed any particular attention to the girl. But his wife realized the condition. In the beginning she tried to hide her emotion, but after four years became sentimentally negative. It was impossible to arouse any feeling of love or hate or fear or anxiety, whatever the cause. After several years of this emotionless state, she could not be made to either laugh nor cry, and although she did her housework and acted as a good mother to her two children, and her memory and judgment seemed intact, and although the girl in the meantime married someone else and moved out west, the woman today walks about with a blank face, very much like a Parkinsonian syndrome.

She has also an anesthetic palate and a bilaterally-contracted visual field. When she talks in her sleep, which is very frequent, she talks of love and cries. At other times, in her sleep, she laughs and becomes very jocular, but as soon as she is fully conscious, she relapses into the aforementioned condition.

#### SUMMARY

Hysteria is a functional nervous disease in which the field of consciousness is contracted, and the subconscious overshadows the conscious mind. The cause is a psychic trauma. It is much like a dream-state or a hypnoidal condition. The strongest outstanding feature is trouble of the will.

# INFECTIONS IN THE TONSILS AND PARANASAL SINUSES IN A SERIES OF CARDIAC PATIENTS

By RAYMOND WILLARD HAWKINS, M.D.,

ROCHESTER N. Y.

THE relation between focal infections in the tonsils and paranasal sinuses, and cardiac disease has long been known, and in the case of the tonsils particularly an extensive literature has been developed. It is the purpose of the writer to point out the findings in a series of cases of organic heart disease examined routinely, and as a comparison, to show the incidence of infected tonsils in an unselected group.

The work on the cardiac cases was done at the Adult Cardiac Clinic of Bellevue Hospital, New York City. To Dr. John Wyckoff, the Chief of that clinic, grateful acknowledgment is made for the use of the material, and for suggestions as to its presentation.

In all cases where sinusitis was reported, except in the ethmoid infections, the diagnosis was confirmed by the presence of pus in the irrigating fluid on washing out the cavity, after a thorough cleansing of the nasal cavity to eliminate the possibility of retained secretion giving a misleading result.

As a criterion for the report of infected tonsils, the following points were considered: (1) Expression of purulent secretion on averting the tonsil with a Coakley tonsil hook. (2) The presence of enlarged tonsillar glands. (3) The amount of injection of the pillars of the fauces. (4) A history of recurrent sore throats. In cases where a recent tonsillar or upper respiratory infection was present, or when there was any doubt as to the diagnosis, repeated examinations were made until the usual condition of the tonsils was determined.

The most comprehensive estimate of the incidence of these types of focal infection may be made by considering the cardiac patient from the standpoint of the etiological factor in his cardiac disease.

As shown in Table I, the greater number of tonsillar infections, 62 per cent, in the rheumatic group is striking. The unknown group, because of the greater frequency of rheumatic heart disease, and its manifold manifestations, probably contains a large number of these cases.

In order to determine the significance of the percentage of infected tonsils found, a control series of 100 cases was worked out. Statistics of the Adult Cardiac Clinic show that practically the entire group of rheumatic cases are included within the ages of ten and forty years. At the Vanderbilt Clinic, patients between these ages were taken at random, just as they presented themselves for treatment in the Medical and Ophthalmological Departments. They were examined according to the same technique, and using the same points in making a diagnosis, as had been employed in the original series. Of the cases examined, 29, or 29 per cent had infected tonsils, as compared to the 62 per cent found in the rheumatic group.

In Table II, a report of the findings in the paranasal sinuses is made.

TABLE I

Etiological Group	Total No of Cases	No of Cases with Infected Tonsils	% of all Cases Having Infected Tonsils	No Having Tonsils Removed	No of Cases with Tonsils not Removed	% of Unoperated Cases Having Infected Tonsils
Rheumatic	122	62	50.8	22	100	62.0
Syphilitic	17	4	23.5	0	17	23.5
Arterio-sclerotic	24	8	33.3	0	24	33.3
Hypertension	4	0	0	0	4	0
Unknown	48	27	56.2	2	46	58.6
Total	215	101	46.9	24	191	52.8

TABLE II

Etiological Group	Total No of Cases	No. of Sinus Infections	% of Sinus Infections
Rheumatic	122	15	12.2
Syphilitic	17	2	11.7
Arterio-sclerotic	24	3	12.5
Hypertension	4	1	25.0
Unknown	48	4	8.3
Total	215	25	11.6

Considering the number of cases in each group on which to base an estimate, there is little variation in the occurrence of sinus disease. Of the 25 cases with purulent sinusitis, 16 had a maxillary sinusitis on one side, five had both sides involved, two had ethmoid infections, one had a pathological process in both the maxillary and sphenoid sinuses on the same side, and one had the sphenoid alone infected. The significant feature is the considerable number of patients with absorption from these cavities.

Another method of approach is by means of a functional classification. The groupings here given are those adopted by the New York Heart

Association Class 1 means the patient is able to carry on ordinary activities, Class 2A indicates slightly limited activities, Class 2B means markedly limited activity, Class 3 are confined to bed, and the potential cardiac cases fall in Class 4

TABLE III

Functional Group	Total No. of Cases	No. of Cases with Infected Tonsils	% of all Cases Having Infected Tonsils	No. of Cases with Tonsils Removed	No. of Cases with Tonsils not Removed	% of Unoperated Cases Having Infected Tonsils
1	16	10	62.5	2	14	71.4
2A	71	36	50.7	8	63	57.1
2B	88	36	40.6	7	81	44.4
3	15	9	60.0	0	15	60.0
4 (Potential)	25	10	40.0	7	18	55.5

Table III gives the result of the findings from this point of view. It is interesting to determine that if an effort is made to establish the usual condition of the tonsils as a standard for comparison, there is nothing in the findings to indicate that the presence of tonsillar infections lowers cardiac reserve. The fact that acute infections occurred was considered in making the diagnosis, but the final record was made when the resting state was established, and the functional capacity at that time was taken. The pathological process, when present in the tonsils examined, had become chronic, and the cardiac mechanism had become adapted to the toxic absorption. The difference would be noted on their removal.

In Table IV, which gives the effect of sinus infections on cardiac function the results of a more acute process can be studied.

TABLE IV

Functional Group	No. of Cases	No. of Sinus Infections	% of Sinus Infections
1	16	0	0
2A	71	11	15.5
2B	88	10	11.3
3	15	3	20.0
4 (Potential)	25	1	4.0

There are no cases of sinus infection, where definite organic cardiac disease is present, without functional loss, and the highest percentage of infections occurs in the group with the most markedly impaired function. Authorities universally agree that the presence of infection has a definite effect in lowering the functional capacity of the cardiac patient, and these findings are entirely in accord with their experience. Here we have clearly demonstrated that the problem is not only that of preventing greater cardiac disease, but of preventing cardiac failure as well.

In the cases of sinus disease found, only a few of the patients felt at all concerned about their nasal condition. Only six had headaches of varying severity. The complaints were mostly the indefinite ones of catarrh and nasal obstruction. Pain, the great stimulus which brings patients in for treatment, was conspicuous by its absence except in the few cases mentioned above.

Those who treat cardiac conditions should in all cases look for possible focal infections in the nose and throat, and should have the co-operation of a specialist. To the specialist comes the responsibility of utilizing every method of diagnosis at his command, and of seeing that prompt and thorough treatment is instituted.

# SUMMARY

In a series of 215 cardiac cases examined routinely at the Adult Cardiac Clinic of Bellevue Hospital, infected tonsils were found in 52.8 per cent of cases, and purulent sinusitis in 11.6 per cent.

In a group of cases with rheumatic cardiac disease 62 per cent had infected tonsils, as compared with 29 per cent in a control series of the same ages.

The diagnosis and treatment of infections of the tonsils and paranasal sinuses in cardiac patients is extremely important not only in preventing greater cardiac disease, but in preventing cardiac failure as well.

## THE CLINICAL USES OF CISTERNAL PUNCTURE

By ARTHUR S. CHITTENDEN, M.D., F.A.C.S.,

BINGHAMTON, N. Y.

**D**URING the past few years our ideas concerning the anatomy and the physiology of the pia-arachnoid system, with its contained circulation, have been considerably revised.

The present general conception appears to be that "the cerebro-spinal circulatory system is a closed system, with impenetrable walls, except at certain points, viz., through fine fasculi or prolongations of the arachnoid into the walls of the venous sinuses, and fasculi prolonged extracranially along the olfactory and auditory nerves and into the lymphatics of the nerve sheaths. The action of the choroid plexus is glandular, and its secretion passes down into expansions of the pia-arachnoid system which act as reservoirs of distribution, whence the fluid is delivered down the length of the cord, or up around the brain convexities along the courses of the surface blood vessels and into the sinuses.

"The cisterns or basilar reservoirs of distribution are three in number, two on the under side of the brain, inaccessible and shallow, and one posterior, accessible, long and deep, and located at the level of the foramen magnum. This pia-arachnoid or spider-web system cannot be adequately observed either at autopsy or during craniotomy because, like some marine forms of fine and succulent structure, loss of turgescence destroys its identity. For the same reason very slight fluid-tension causes circulatory block and oedema.

"Unlike the renal circulation which filters its refuse *only* into and out through the kidneys, the cerebro-spinal fluid passes in its *entirety* into the great venous sinuses. As the arachnoid passes over the cortex and along the deeper vessels, its fasculi or minute prolongations dip down into the parenchyma whence it receives a fluid differing from itself, a sort of brain juice containing waste products. Thus is established a communication between intra-cellular brain metabolism and the vascular system, this is accomplished by selective exosmosis on the brain side, and complete osmotic transudation on the vascular and lymphatic side."

A very large part of the damage wrought in the brain and cord through infection, neoplasms,

trauma and intoxications is brought about by blockade of this system. Exudates, transudations of blood, pressure of tumors, and osmotic disturbances from intoxications give rise ultimately to circulatory blockade, either focal or massive, causing a rise of intra-cranial pressure. Even a casual review of the sites of these blockades together with the associated causes, lie far beyond the limits of this paper. Quincke's lumbar puncture, although applied at a far outlying point in the cerebro-spinal system, gave us the first safe and direct approach to the pia-arachnoid spaces. Many will recall the ceremony, almost sacramental, which attended its early employment. Today few of us would care to go about our regular work unequipped with spinal needles and a knowledge of their uses. The value of lumbar puncture cannot be over stated, either from the standpoint of drainage, diagnosis or remedial approach. It will never be superseded. Its adoption has been slow, over thirty years, and in most acute disturbances of consciousness or locomotion it may be more often profitably used than any other simple procedure.

This paper concerns itself with restating the importance of another procedure having the same general uses as lumbar puncture—that of cisternal puncture. This approach will probably not be so generally employed as is lumbar puncture, perhaps it should not be, because it is not free from danger. The writer has, however, never known or heard of an accident arising from this method, although a mishap is readily conceivable.

Puncture of the great cistern was originally employed as an easy way of obtaining cerebro-spinal fluid from experimental animals. Almost immediately, however, application was made to the human patient. The width of the aperture, 1 cm., between the base of the skull and the atlas, together with the depth of the cistern, 1.5 cm., and the resistance of the occipito-atlantoid ligament, offer adequate safeguards to those who are familiar with puncture at the lumbar level. This great cistern is the first to receive the newly formed fluid as it arrives through the foramina of Magendie and Luscha, and is the chief dis-

tributing reservoir. Access to it means immediate approach to the very center of the cerebro-spinal circulation. The *spinal* pathway leading from the cistern is the longest of its ramifications and lumbar puncture is twenty inches removed. The usefulness of cisternal puncture in the localization of brain tumors, or in the differentiation of obstructive and communicating hydrocephalus, will not be here considered because these states require other combined and more difficult procedures higher on the skull.

Simple cisternal puncture, or combined with lumbar puncture, in addition to its advantages of immediate basilar approach, eliminates the difficulties of spinal pia-arachnoid block. Blockade of the spinal pathways is much more common than one would suppose. It occurs often in meningitis, encephalitis, intra-cranial hæmorrhage, spinal tumor, and in fracture or caries of the spine. Cranial hæmorrhage and infection commonly cause obstruction at the margin of the foramen magnum and in the thoracic spine, in the case of tumor, caries, or fracture, obstruction is of course at the point of pressure.

*Suspected Spinal Tumor.* A comparison of the fluids drawn from the lumbar and cisternal needles as to the amounts of albumen contained, will, in the case of block by tumor, show much more albumen in the lumbar fluid. Often the lumbar fluid will be definitely yellow in color—the "Xantho-chronia of Proin."

*Spinal Block of Meningitis.* Lumbar puncture may yield a small amount of fluid and under pressure. Immediate cisternal puncture, however, often gives a copious flow and under great pressure. Under these conditions serum administration by the lower route would be ineffectual because it would not reach the cistern or the convexities, nor would the puncture reduce the intra-cranial pressure.

*Spinal Block of Intra-Cranial Hæmorrhage.* Fulminating cases of meningo-encephalitis with marked hæmorrhage can be saved by prompt, repeated, high puncture, low puncture will not suffice because the blood coagulates about the brim of the foramen. Four of these cases have been seen in the past two years. In each the sequence has been the same—swift onset, spasticity, difficulty in swallowing, unconsciousness, and ocular palsies. In three the blood from the cistern passed under great pressure through a

large needle, and the cultures were sterile. The fourth case was not punctured, but died, and the diagnosis was verified at autopsy. The third was punctured once only and returned to consciousness whereupon further puncture was refused by the family. She promptly re-established the earlier clinical picture and died. The first two in this series made good recoveries. The hæmorrhagic features of these cases would probably not have been revealed or relieved by low puncture.

Subdural hæmorrhage, due to head injuries, accumulating in the posterior fossa and causing death, is often surprisingly small in its mass. Clotting may soon occur about the foramen margin and medullary pressure becomes apparent in the stertor of the breathing. Jackson of Chicago has unquestionably shown the enormous value of lumbar puncture in cases of intra-dural hæmorrhage. This procedure avoids temporal decompression (which often does not decompress the posterior fossa, and especially does it afford decompressive relief when the critical state of the patient renders subtemporal decompression on unthinkable. Semi-clotted, thick blood will often not drain well along the spinal pathways and down to the lumbar needle. The writer has demonstrated, to his own satisfaction at least, that prompt cisternal puncture will relieve medullary compression by a copious flow of thick blood, when the flow from a previous lumbar puncture had ceased and things had come to an impasse. This impression is not based on a few isolated cases but upon a considerable series afforded through the courtesies of my colleagues at the Binghamton City Hospital. The total amount of blood withdrawn is often not more than 30 c c. Experiments in spinal fluid displacement show, however, that an even smaller mass gives rise to serious symptoms.

Cisternal puncture may be readily done in these fracture cases with the patient in the lateral position, the needle being left in place for several hours. Change of the patients' position from the lateral to dorsal or contra-lateral position should not be permitted under twenty-four hours. The writer has seen sudden death follow change of position in patients who were apparently reacting favorably eight hours after puncture. Similar mishaps follow moving patients after cerebellar decompressive procedures for brain tumor.

## THE CLINICAL USES OF CISTERNAL PUNCTURE

By ARTHUR S CHITTENDEN, M D, F A C S,

BINGHAMTON N Y

**D**URING the past few years our ideas concerning the anatomy and the physiology of the pia-arachnoid system, with its contained circulation, have been considerably revised

The present general conception appears to be that "the cerebro-spinal circulatory system is a closed system, with impenetrable walls, except at certain points, viz, through fine fasculi or prolongations of the arachnoid into the walls of the venous sinuses, and fasculi prolonged extracranially along the olfactory and auditory nerves and into the lymphatics of the nerve sheaths. The action of the choroid plexus is glandular, and its secretion passes down into expansions of the pia-arachnoid system which act as reservoirs of distribution, whence the fluid is delivered down the length of the cord, or up around the brain convexities along the courses of the surface blood vessels and into the sinuses

"The cisterns or basilar reservoirs of distribution are three in number, two on the under side of the brain, inaccessible and shallow, and one posterior, accessible, long and deep, and located at the level of the foramen magnum. This pia-arachnoid or spider-web system cannot be adequately observed either at autopsy or during craniotomy because, like some marine forms of fine and succulent structure, loss of turgescence destroys its identity. For the same reason very slight fluid-tension causes circulatory block and oedema

"Unlike the renal circulation which filters its refuse *only* into and out through the kidneys, the cerebro-spinal fluid passes in its *entirety* into the great venous sinuses. As the arachnoid passes over the cortex and along the deeper vessels, its fasculi or minute prolongations dip down into the parenchyma whence it receives a fluid differing from itself, a sort of brain juice containing waste products. Thus is established a communication between intra-cellular brain metabolism and the vascular system, this is accomplished by selective exosmosis on the brain side, and complete osmotic transudation on the vascular and lymphatic side"

A very large part of the damage wrought in the brain and cord through infection, neoplasms,

trauma and intoxications is brought about by blockade of this system. Exudates, transudations of blood, pressure of tumors, and osmotic disturbances from intoxications give rise ultimately to circulatory blockade, either focal or massive causing a rise of intra-cranial pressure. Even a casual review of the sites of these blockades together with the associated causes, lie far beyond the limits of this paper. Quincke's lumbar puncture, although applied at a far outlying point in the cerebro-spinal system, gave us the first safe and direct approach to the pia-arachnoid spaces. Many will recall the ceremony, almost sacramental, which attended its early employment. Today few of us would care to go about our regular work unequipped with spinal needles and a knowledge of their uses. The value of lumbar puncture cannot be over stated, either from the standpoint of drainage, diagnosis or remedial approach. It will never be superseded. Its adoption has been slow, over thirty years, and in most acute disturbances of consciousness or locomotion it may be more often profitably used than any other simple procedure

This paper concerns itself with restating the importance of another procedure having the same general uses as lumbar puncture—that of cisternal puncture. This approach will probably not be so generally employed as is lumbar puncture, perhaps it should not be, because it is not free from danger. The writer has, however, never known or heard of an accident arising from this method, although a mishap is readily conceivable

Puncture of the great cistern was originally employed as an easy way of obtaining cerebro-spinal fluid from experimental animals. Almost immediately, however, application was made to the human patient. The width of the aperture, 1 cm, between the base of the skull and the atlas, together with the depth of the cistern, 1.5 cm, and the resistance of the occipito-atlantoid ligament, offer adequate safeguards to those who are familiar with puncture at the lumbar level. This great cistern is the first to receive the newly formed fluid as it arrives through the foramina of Magendie and Luscha, and is the chief dis-

pital to serve a wide territory. There are in this State large, flourishing, prosperous and progressive cities still sending the mentally sick to penal institutions, because no other provision has been made.

The provision for preventive work comes late in this consideration of the topic when, if importance were the sole criterion, that question should have had first thought. Prevention comes after recognition. It is only after the calamity that man thinks of measures designed to avoid its repetition. Even if the preventive measures are simple and sure they are often delayed. Prevention of the development of mental cases is neither easy nor sure. One often has to wait long for results, the steps are taken in the dark and at best are far from being bold strides toward universal mental balance. In the mental disturbances which we now think are due to faulty adjustments the effort should be made early and the result is something to be hoped for more than confidently predicted. When a psychiatrist sees a person struggling with a problem and is able to help him by advice, he does not flatter himself that the individual would not have made an adjustment without his assistance. People have struggled and have made satisfactory adjustments before now and they will continue to do so until the end. If we can help, perhaps shorten, or with psychiatric advice give the necessary assistance to help with loads, it is an

effort distinctly worth while. In this work the clinic assumes first place. Recognition that something is wrong may take place in the school, the shop or the office, and all of these places cannot have a psychiatrist, but the knowledge that there is a clinic where advice may be had can be widespread.

There is, however, one concrete suggestion, which easily can be put into effect and one which will give results. Without any attempt at reformation of character or changing the public thinking, the number of cases of general paresis can be materially reduced. It would, of course, be highly desirable to succeed in placing syphilis in the class of rare diseases or to eliminate it entirely. That may come, but while we are waiting we can impress upon physicians the fact that the invasion of the central nervous system occurs early in the course of the luetic infection and that cases should not be discharged as cured until the spinal fluid has been examined and found to be negative. Physicians are alert to the interests of their patients and most doctors estimate the progress of the anti-syphilitic treatment by blood Wassermans. If they were to make a spinal fluid Wassermann after the blood becomes negative, treatment would not be stopped too early, and the number of patients dying annually of general paresis, tabes and cerebral syphilis would be reduced.

## Deaths

CRUIKSHANK, WILLIAM J, Brooklyn, New York University, 1880, Fellow American Medical Association, Fellow American College of Physicians, Brooklyn Pathological Society, Member State Society, Consulting Physician, Wyckoff Heights and Broad Street Hospitals. Died March 3, 1925.

DEVNETT, WILLIAM SAWYER, New York City, Harvard, 1874, Fellow American Ophthalmological Society, New York Ophthalmological Society, Member State Society. Died March 6, 1925.

HYNES, EDWARD G, Brooklyn, College of Physicians and Surgeons of New York, 1900, Fellow American Medical Association, Member State Society, Visiting Gynecologist, Coney Island Hospital, Associate Surgeon, St Mary's Hospital. Died March 14, 1925.

MYERS, EDWARD E, New York City, Harvard, 1901, Fellow American Medical Association,

Member State Society. Died February 24, 1925.

PORTER, WILLIAM EVELYN, New York City, College of Physicians and Surgeons of New York, 1888, Fellow American Medical Association, New York Academy of Medicine, Member State Society, Alumni Association of Bellevue Hospital. Died March 26, 1925.

SEVERANCE, BENJAMIN W, Phoenix, Cleveland Homeopathic College, 1882, Member State Society. Died February 18, 1925.

STRATMANN, CHARLES FRANCIS, Brooklyn, College of Physicians and Surgeons of New York, 1906, Fellow American Medical Association, Brooklyn Pathological Society, Brooklyn Surgical Society, Member State Society, Alumni Association Norwegian Hospital, Assistant Attending Surgeon Norwegian Hospital. Died March 28, 1925.

# COMMUNITY PROVISION FOR MENTAL ILLNESS\*

By FREDERICK W PARSONS, M D

BUFFALO N Y

IN considering those steps which a community should take to provide adequately for the cases of mental illness threatening or developing in its midst, mention must be made of measures which are the special topics of other papers, read or to be read, during the course of this symposium on the relation of the state hospital to the community. The special features of such topics will be more completely covered by the essayists to whom those subjects have been confided. An answer to the question, "What facilities should a community provide" might formulate a conception of such perfection and of attainment so nearly impossible that efforts in that direction would be discouraged. In the local situations, which will be mentioned and discussed, the State hospitals play only the minor rôle of advisor, giving moral support to movements intended to promote the betterment of conditions and supplying personnel when the local resources are deficient.

All civilized societies make some provision for mental cases and that provision varies with the degree of civilization, the size and wealth of the individual community and the density of population. Much of this provision has not been altruistic. It was dictated by the desire to exclude those persons whose behavior did not conform to the standards then in force. The provisions were largely for the mass rather than for the individual. No community does its full duty when it limits its activity to the apprehension and the seclusion of persons who, by reason of mental ill health, threaten its peace and security. It is necessary, primarily, to recognize that in all communities there are people who, for certain reasons, have difficulties of adaptation with which they have to struggle. They may succeed in weathering storms and stresses or they may fail. They will have a much better chance to succeed if the community provides all of the help which can be given.

The general problem of what procedures a community should undertake can be considered under four main groupings

- 1 Provisions for discovery
- 2 Provisions for examination
- 3 Provisions for temporary care
- 4 Provisions for prevention

It might be thought that to discover the mentally sick persons resident in a community would be a relatively simple matter, but there are other types than the turbulent. They are easily located, in fact, it is not possible to miss them. The

problem is to locate those individuals who are trying to master a mental difficulty of which they perhaps, alone are conscious. Such persons may not realize that an inadequacy which may be thought to represent a physical ailment is but the outward evidence of an emotional struggle. This is the individual for whom the clinic is best suited, and a clinic fails to fulfill its entire purpose when it does not search out individuals of this class. It should make its presence known. Social agencies must know of the establishment of the clinic and when and where its resources are available. In addition, the prospective patient should be given an opportunity to know where to go in his difficulty. Physicians, the clergy, the courts, teachers, the shop and social agencies will supply the majority of the patients.

Provision for a more extended examination than the clinic yields and provision for temporary care are here considered together. Not all cases will require other opportunities for examination than those afforded by the clinic, nor do all cases need provision for temporary care. Certainly in some instances it is necessary to have a more thorough examination than is possible in a clinic and frequently home care is impossible. For the sick, hospitals are provided and for the provision for the temporary care now under consideration we must turn to the hospitals. There has been a disposition to think that the temporary care of persons mentally sick is a proper function of jails, police stations and almshouses, and even if separate quarters in such institutions have been provided the continued use should be discouraged. The care of the mentally sick is not a police question. It is a health problem with which only medically trained persons are competent to deal. Unfortunately, all of the medically trained do not completely realize what can be done with and for the mentally sick. Aside from financial restrictions, and they are not insurmountable, no moderately sized city with a hospital should be without a psychiatric ward where cases can be thoroughly examined, carried through a short mental illness or properly cared for while awaiting transfer to a State hospital. The psychiatric ward can be incorporated into and made a part of the general scheme without annoyance to the other departments. Such a ward in the Buffalo City Hospital, with forty patients, having a dispensary and diagnostic clinic below it and a medical ward above, operates without complaint. Small communities cannot be expected to provide care for its mental cases when it does nothing for those physically sick, but with good roads, automobiles, train and trolley services, each part of a county is brought into relation with other parts, making it possible for one hos-

## GRADUATE MEDICAL COURSES

Every physician feels the need of instruction in not only the newer phases of medicine, but also in the elements of the more common specialties. It is not enough for a physician to read of the newest discoveries in order to be up-to-date, he must also refresh his memory regarding knowledge which he once had vividly in memory, but which through lack of use has become uncertain. And it is not to be considered reprehensible that a physician loses his keenness along lines that he has no occasion to use for years. If, for example, he was trained in genito-urinary work and later located in a rural district where he could not practice his specialty, he would lose his skill in the course of years. Now suppose his rural town became a prosperous center, and he wished to resume the practice of his former specialty, he would then wish to do graduate study along his former line of work.

The post-graduate medical study which we have in mind does not have for its object the imparting of a knowledge of new discoveries in order that the physician may ride the foremost crest of the wave of progress. We have known physicians who have adopted every new procedure. They have bought a chlorine apparatus with which to treat colds, they applied Lane plates for fractured bones, and got osteomyelitis as a result, and they adopted the intramuscular use of salvarsan and produced abscesses. The post-graduate education which we have in mind will enable the practitioner to choose the wheat from the chaff of new procedures.

We have in mind the needs of the family doctor, rather than the specialist. The family medical advisor is now called upon to express his opinion along every phase of medical practice. He need not be a specialist in any line, unless it be that of general internal medicine, but he is expected to recognize the signs of danger while they are yet far off, and if he does not understand a condition, he is expected to suggest what specialist shall be called.

It takes knowledge to enable a physician to know when to call a specialist, and when to manage a case himself. It takes thought and considerable practice to make those elementary tests and examinations which reveal the existence of trouble and the need of calling a specialist who is able to judge the finer details of the patient's condition, and assume the responsibility for his welfare.

The periodic health examination movement is revealing to physicians both the need of knowing the elements of several specialties and the comparative ease of acquiring such a degree of knowledge of a specialty as to recognize that a case belongs to a particular branch of medicine. Eminent specialists recognize the necessity of in-

forming general practitioners regarding the early signs which suggest serious trouble in an organ. The genito-urinary men, for example, are urging physicians to give heed to the warning signs associated with urination, such as pain, or increased frequency, or transient cloudiness, or blood. These signs are fully as evident to a general practitioner as to a specialist. In fact, they are evident to every patient no matter how ignorant he is. The difficulty lies in the interpretation of the symptoms and signs. The doctor is not up to the common standard in his practice of medicine if he does not take serious note of these symptoms and refer his case to an honest specialist.

The need of graduate medical education is not confined to the family physician. Every specialist needs it in the lines which he does not practice. It is becoming unfashionable for a specialist to boast of his ignorance of every branch of medicine except that which he practices. He cannot be a real specialist unless he knows the whole body. There may not be an extremely close relation between, for example, the eye conditions and orthopedics, but we would have an increased confidence in our oculist if we felt that he understood feet, and hearts, and kidneys, a little better than the ordinary physician. It is especially in the smaller cities and rural places that a specialist needs to have considerable knowledge of other conditions besides those in his own line.

These thoughts have been in the minds of the leaders of the Medical Society of the County of Kings as they have devised a new system for graduate medical education in co-operation with the Long Island College Hospital Medical School. The special feature of their plan is that the instruction is held at a time and place that suits the physician who must stay at home and earn his living while he takes his instruction. It is not intended to make specialists out of the students, but it gives family physicians instruction in the elements of the specialties which they will use. There are courses in the heart, the kidneys, venereal diseases, orthopedics, pediatrics, and so on through the whole ranges of specialties. The courses are open to physicians from all parts of the Island. The fee charged is only sufficient to pay the bare expenses of the course.

The committee that has the graduate instruction in charge felt that the physicians of Nassau and Suffolk counties could not afford the time or money required to come to Brooklyn for their instruction, and so they have offered to send instructors anywhere on the Island to any group that wishes to take up a line of study. The first group that has been formed consists of the members of a local society, the South Side Clinical

## THE ANNUAL MEETING

Preparations for the annual meeting of the Medical Society of the State of New York are progressing satisfactorily, and the meeting promises to be one of the best that has ever been held. Reservations at the Syracuse Hotel are being taken and those who expect to be present will do well to engage their rooms in advance. A list of the principal hotels is printed on page 587 at the end of the scientific program. There will be the usual features, including the scientific sessions and the annual banquet. But in addition to these, plans are almost perfected for a tuberculosis exhibit and demonstration all day on Thursday. In this exhibit an unique array of material covering every phase of tuberculosis has been brought together. Lecturers and demonstrators have been secured, specimens and pic-

tures, X-ray films and microscopic slides. It is also expected to have a multiple stethoscope by which a whole roomful of physicians may listen to the lungs at the same time.

What is common is likely to be considered commonplace. Tuberculosis is one of the most common of all the diseases which every doctor treats. It has no spectacular features and it brings neither profit nor glory to the physician. Success in its treatment requires attention to ordinary details which doctors are likely to overlook because they are almost self-evident. The demonstration at the annual meeting will give interest to a subject that is too often avoided, and will give the physician a mental picture of the conditions which are present in every stage of a case of tuberculosis.

F O

each County Legislative Chairman at the semi-annual meeting of his individual county society in the early summer, and plans should be laid at that time for future action in the fall. It is for each county society to judge of the action of its legislators and of its own officers and in the freedom of the State Society and of the body politic of the State as citizens, it is for the county society to judge what its action will be in relation to its legislators.

Your Committee on Legislation, voluntary in the work that it gives to the physicians at large, asks that the delegates from the county societies to the annual meeting have in hand from the individuals of the county society or from the officers of the same, or the Chairman of the Legislative Committee, such criticisms, suggestions and the

like as may seem of import to the individual county society or in relation to the House of Delegates as a whole, and that the delegates be prepared to file in writing such propositions as are handed to them in order that the Reference Committee to which the report of the Committee on Legislation is ordinarily assigned may deal with these suggestions and in their report to the House of Delegates may bring them up for open discussion. Only in this manner will the Medical Society of the State of New York keep its enthusiasm at highest pitch and raise itself and its individual members from the narrow ruts of medical practice into which it is so easy to fall and to 'let the other follow do the thinking and the acting'

J N V

### 1925 LEGISLATIVE SEASON CLOSES

Not until the adjournment of the Senate at 4 P M Friday, March 27th, was it definitely known that the Dunmore bill, in which we had such great interest, would not be enacted into law this year. The bill was passed by the Assembly about midnight Thursday and introduced to the Senate on Friday morning as an Assembly message. Attempt was made at the time of its introduction to advance it in the Senate to third reading, but was lost by the objection of Senators Fearon and Gibbs, after which it was referred to the Public Health Committee, who reported it again to the Senate a few hours later together with the Gibbs Drugless Therapy bill but by the objection of Senator Fearon it was not admitted to the floor for discussion, but referred to the Committee on General Orders, from which it proved impossible to have it extricated, in spite of the fact that every known parliamentary procedure was invoked. Governor Smith also was urgent and sent an emergency message to the Senate urging its consideration and passage, and there was plenty of evidence that a majority of the Senate would support the bill.

Since there was no debate in the matter, it is impossible to state what actually incited the objection raised by the two Senators but it is interesting to know that each was sponsor for a bill that would have licensed chiropractors.

At the time the Dunmore bill was approved by the Assembly it also considered bills incorporating the Dunmore bill, but amended so as to provide for licensing chiropractors.

The Dunmore bill was the first to be voted upon and was passed by a vote of 107 to 37. The sentiment of the Assembly was such that a slow roll-call was not called for, hence there is no record as to who voted for or against the bill.

The Esmond bill was next to be considered, but powerful opposition in the Assembly induced

Mr Esmond to allow it to be recommitted rather than take a final vote at that time.

There was more uncertainty as to the strength of the Jenks bill, hence it was submitted to a slow roll-call, which resulted in 50 in favor of and 85 opposed to the bill. Both Mr Esmond and Mr Jenks immediately moved that the votes on their bills be reconsidered. These motions were laid on the table for the time. Mr Esmond attempted to have his bill brought out on Friday, but was defeated again by a large vote. No further effort was made to bring the Jenks bill out.

The other bills that aimed to secure a license for chiropractors and other cultists, namely

#### In the Assembly

The Nicoll Chiropractic bill,  
The Esmond Healing Art bill,  
The Jenks Chiropractic bill,  
The Bolton Chiropractic bill

#### In the Senate

The Bouton Chiropractic bill,  
The Fearon bill,  
were never reported out of committee.

The combined thought and efforts of those who truly have the interest of public health at heart, have again failed in the desire to more strongly bulwark the same, but the deep interest taken in the Karle-Dunmore bill by more of the legislators than ever before augurs well for the solid defense desired by the state citizenry in protecting the uneducated and helpless from the prey of the charlatan. We have given our best efforts to this rightful legislation in no compromising terms and it is to be hoped we do not reverse our position.

The amendments to the Workman's Compensation Law which would have provided for the free choice of physician did not pass, to our

Society, which is practically a sub-group within the Suffolk County Medical Society, and is composed of those who live in the southwest section of the county and form the staff of the South Side Hospital at Bay Shore. This group will take up the study of pediatrics, and will meet once a week for a clinical demonstration upon cases brought by the members of the class.

The Brooklyn plan of graduate instruction does not sell itself to physicians. The idea must be presented to the doctors before they will enroll in any considerable number. It is well adapted to any section of New York State, and the Medical Society of the State of New York is the official body which could sponsor it with authority and grace. F O

## HISTORY OF 1925 LEGISLATURE

The history of the legislature of this State for 1925 is now written and in many respects can be said to be satisfactory to the vast majority of the lay people and the medical profession of the State.

Again has New York State through its representatives upheld the standing of the State in its refusing to break down the definition of the practice of the healing art and in refusal of recognition of individual cults who loudly proclaim the efficiency of this or that method of treatment for any and all types of deviation from the normal health standards.

That those who have been deeply interested in seeing that the public health of this State was conserved in advancing medical standards, and in the denial to cultists of their proclaimed rights to foist themselves upon the public in defiance of known physical and scientific principles, have lost in their efforts politically to impress the legislators with what is right and true, is no reason in the future to lower standards or talk of compromise when the right principle is involved.

The Medical Society of this State should be congratulated in its efforts and desires to combine with all such groups who look forward into the future and who can assuredly wait for that time when the right will assert itself and be put into laws.

In our form of government the individuality of one placed in high position to pass on questions of importance to the people at large, whether it be a social group or as an elected representative of the people, may be swayed many times to take a position other than the broad viewpoint of the State at large.

The House of Delegates and the Council of your State Medical Society gives careful thought, and it should so give this careful thought to the choice of those whom they would care to elevate to positions of prominence within their body. It is through these elected representatives of the medical profession that the voice of the culosis exhibit projected into State thought, and Thursday. In the physician of the present day is material covering ever far greater import to the been brought together. Case fifty years ago strators have been secured, spranced in thought

more rapidly than in any other line of endeavor, and he it is who must be in touch with every phase of life, as business, sciences, advances along professional lines and thought, and like highways, such as no other man of the present day.

How often do we see the business man so immersed in his own selfish interests as to be unversed in the life of his city and refusing to participate in civic, charitable or political activities, and how many are those with whom the doctor has come in contact who seek to evade jury duty and like compulsory matters which bind up our government into its whole?

Just so do we find the legislators of varying degrees of education, of representation in the business and professional world of varying selfish desires on their parts to advance their own positions, be it civic, political or mercenary.

And so as a Medical Society, through the Committee on Legislation, has this been portrayed during the moving picture of the legislature of 1925.

With the ringing down of the curtain there is food for conjecture and deep thought on the part of those who have been the actors and the audience during the unfolding of the play. And this conjecture with resulting judgments should be put in play by the various county medical societies of the State Society during the coming months, for opposition to right thinking and selfishness in thought and action is as subtle and persistent in endeavor as has ever been put forward by any opponents in State or Nation.

With the cessation of legislation the burdens of the State Committee on Legislation and of the County Legislative Chairmen become lessened. But it is not to be thought that work should absolutely cease and these burdens be laid aside until another session convenes, and the same questions are to be met as in these years past.

A county society little knows of the work asked of its County Legislative Chairman, and while in the main each one has given much time to action and thought as to how to act properly, it rests with each County Society to judge as to the results of its own individual Chairman's efforts.

A resume of the year's work in a report written and ready for filing should be delivered by

each County Legislative Chairman at the semi-annual meeting of his individual county society in the early summer, and plans should be laid at that time for future action in the fall. It is for each county society to judge of the action of its legislators and of its own officers and in the freedom of the State Society and of the body politic of the State as citizens, it is for the county society to judge what its action will be in relation to its legislators.

Your Committee on Legislation, voluntary in the work that it gives to the physicians at large, asks that the delegates from the county societies to the annual meeting have in hand from the individuals of the county society or from the officers of the same, or the Chairman of the Legislative Committee, such criticisms, suggestions and the

like as may seem of import to the individual county society or in relation to the House of Delegates as a whole, and that the delegates be prepared to file in writing such propositions as are handed to them in order that the Reference Committee to which the report of the Committee on Legislation is ordinarily assigned may deal with these suggestions and in their report to the House of Delegates may bring them up for open discussion. Only in this manner will the Medical Society of the State of New York keep its enthusiasm at highest pitch and raise itself and its individual members from the narrow ruts of medical practice into which it is so easy to fall and to 'let the other follow do the thinking and the acting'

We have given our best efforts to this rightful legislation in no compromising terms and it is to be hoped we do not reverse our position.

The amendments to the Workman's Compensation Law which would have provided for the free choice of physician did not pass, to our

regret But on the other hand we should be quite satisfied with our efforts in preventing any serious consideration of the following

The cult bills,  
The birth control bill,  
The anti-vivisection bill,  
The laboratory supply bill

We have the satisfaction of knowing that we introduced, or aided in securing the passage of, the following

Medical Society Censors bill,  
The amended Public Health Nurses bill,  
The Cadaver bill,  
The Workmen's Compensation Silicosis bill  
J S L

### THE CONSULTANT'S FEE

Patients often complain about the fees charged by consultants to whom they are sent by their family physician. When a patient goes to a consultant of his own accord, the family physician of course has no responsibility in the matter. If a poor patient puts on his very best clothes, and is taken to the private office of the consultant through the kindness of a rich neighbor who loans his automobile and chauffeur, can the consultant be blamed for charging the maximum fee? He judges the stranger by his appearance.

If the family physician sends his patient to a consultant, he owes a duty to both the consultant and the patient. To the patient he owes the duty of ascertaining the consultant's fee, in order that the patient may be prepared to pay it without embarrassment. The argument, of course, is that he shall not go to the consultant unless he is satisfied with what the fee is to be, and that, fur-

ther, he shall not expect unusual attention for a reduced fee.

To the consultant the family physician owes the duty of informing him about the financial ability of the patient. A city consultant cannot judge the financial status of a rural patient by his dress and environment. The plainly dressed, awkward gentleman may be the president of his bank in the country, and the lady in the limousine may be the poor laborer's daughter in the loaned car. Much embarrassment to everybody will be avoided if the family physician will make the arrangements with the consultant for the details of the patient's visit, including the fee.

We are constrained to write this because we believe that it is to the best interests of both the family doctor and the consultant, as well as of the patient, that the general practitioner shall prove his interest in the case by attending to all possible details for the patient. F O

### A NURSE'S DUTIES

We wonder if trained nurses have forgotten their duties as high class maids-in-waiting upon the sick? That is the primary duty of every nurse, and is all a so-called practical nurse is supposed to know.

Is any bedside nurse so highly trained that she can afford to neglect her maid-in-waiting duties? Are those duties so menial that she does not care to do them?

Why is it difficult to get good bedside nurses?

There is much dissatisfaction all over New York State over the shortage of bedside nurses. The shortage also extends into the field of public health nursing, but it is doubtful that there would be enough bedside nurses if all the public health nurses should go back to nursing the sick.

We wonder if the requirements for graduation as a trained nurse are not entirely too high? The answer depends on what kind of nurse is wanted.

A nurse's accomplishments are along two lines, first as a maid-in-waiting, and second, technical, to enable her to carry out the doctor's orders.

It would seem that both of these subjects could be well acquired in two years. Why then spend three years in training? The third year

is spent in the study of subjects, such as bacteriology, which are medical and of no practical use to the nurse. Why does she need to study them?

The theoretical instruction is of value to a nurse who expects to be a public health nurse. Why not give the scientific and theoretical subjects as a post-graduate work to those who expect to be public health nurses or to do supervisory work?

Is there need that a trained nurse should have months of practice in every known specialty?

Why should she go to an insane asylum to take care of crazy people? Why should she study specialties in her fundamental course?

We are simply repeating questions which we hear asked almost daily. The committee of the Erie County Medical Society has devised an answer to the question, and other physicians are proposing other answers. (Page 590)

Our suggestion is that there be two grades of nurses, or possibly even three. Why not train one set for a year to be maids-in-waiting to the sick, another set for two years to do scientific bedside nursing, and another group for three years to do supervisory and public health work.

F O

# LEGAL

By GEORGE W. WHITESIDE, Esq.  
Counsel Medical Society of the State of New York

## FIVE THOUSAND PHYSICIANS SHOULD THINK THIS OVER.

Four years ago the medical profession in this State faced a crisis in meeting law suits brought by patients against doctors. Lawyers who had found it lucrative to bring suits based on negligence were confronted with a dwindling practice due to numerous changes in the law, not the least of which was the passage of the Workmen's Compensation Act. The attention of such lawyers was directed to a new field—that of malpractice. Some insurance companies that had written policies of protection against such law suits deemed it necessary to treble their rates. The cost of malpractice defense through the State Medical Society was increased through the increased number of cases to an amount beyond what it could afford. Some insurance companies were abandoning entirely the writing of such protection. At this time it was with no little difficulty that we consummated with the Aetna Life Insurance Company the group insurance plan which brought insurance protection against malpractice suits within the means of every member of the State Society. The insurance company regarded this somewhat as a bold experiment, which they were assuming heavy potential liabilities, but were willing to undertake a trial.

The experience for the past four years has been directed to the placing of malpractice defense on a scientific basis, both as to methods of intensive preparation on the law and the medicine of the cases, as well as on the financial basis upon which the insurance can be written. There is no mystery about the computations by which rates are made under this plan. There is no thought on the part of the company of gouging the doctors, or on the part of the doctors of mulcting the company. The highly scientific principles governing insurance are applied to the facts, and conclusions are arrived at which the facts justify.

It is pleasing that at a recent conference with the representatives of the company, when costs for suits and claims past and pending and for projected future law suits were computed, it was found for the coming year it would not be necessary to increase the rates of such insurance. Four years experience helps to stabilize this type of insurance and place it upon a basis of cost. One company dealing in a commodity may afford to sell below cost in a given locality to overcome competition, but as a settled policy of business it cannot continue such practice. Other insurance companies may, in a similar way, for a short time, undertake to undersell the State

group plan, but they cannot ultimately escape, if they desire to continue to do this type of business, the necessity of basing their rates upon the cost of insuring the hazard. Companies now doing the business below cost would have to make future rates sufficiently high to make up for the loss which they would occasion by such practice.

The members of the State Society have the benefit of directing the policy of the defense of malpractice suits, of participating in the tabulation of the costs upon which are based the rates, and in addition, have a policy that is broad and liberal in its terms and backed by the faith and credit of a financially powerful and honestly administered company.

The situation existing today, by which this insurance is available to the members, is not the result of mere accident, but is the result of four years of constructive work on the part of the Executive Committee and council of the State Society and of the legal department of the Society, together with the co-operation and good faith of the Aetna Life Insurance Company. Without these elements this plan would have gone on the rocks and the members of the Society today would have found it difficult to procure adequate protection, except at excessively high rates.

It seems strange, under these circumstances, that upwards of five thousand members of the State Society are still either unaware of the benefits to themselves of such protection, or are indifferent to the legal hazard under which they are practicing medicine.

Nothing that has been written in this column sufficiently expresses the ease with which a clever lawyer can, in a malpractice suit against a doctor, place in jeopardy that intangible, yet priceless possession—a doctor's reputation for integrity, skill and care, and likewise subject the doctor to the hazard of a lay jury's decision.

It is the purpose of your counsel to thwart this effort when injustice is sought to be done to the physician, and to mobilize the force of his office for the intensive preparation and trial in the defense of such a doctor, and fortunately, it is within his power, where an injury has been done to a patient for which a doctor is legally responsible, to be able fairly to compensate the injured party. This plan benefits the doctor, benefits the just claimant, and is of inestimable value to the profession of the entire State.

We have no interest of a financial character in the writing of the policies. We receive no profit and have no participation in that phase of

the insurance. So we feel we can urge its adoption, support and acceptance by each doctor, keeping in mind his interest and his welfare.

### NON-PREGNANCY, LEUCORRHOEAL DISCHARGE, ATTEMPT TO CURETTAGE, SUBSEQUENT OVARIECTOMY

In an action instituted against a physician it was charged that the plaintiff had consulted him with reference to the fact of her failing to become pregnant though she had been married for some time, that the physician after examination diagnosed her case as being one where an unnatural condition of the womb existed and further advised the application of certain electrical treatments for the elimination of the patient's complaint, that the patient submitted to the application of violet ray and after eleven treatments was advised by the physician that these treatments having failed to produce the desired effect, a curettage would be necessary, that the patient, relying upon the advice of the physician, consented to the performance of the operation, that arrangements were made for the performance of such operation, the attending physician to act as anaesthetist and a gynecologist to perform the curettage, that both the physician and the gynecologist were negligent in the performance of the operation and that by reason thereof the patient was confined to her bed for many days and suffered from fever and considerable pain. It was claimed that a few days thereafter the physician advised that the patient's condition was satisfactory and that she would be all right within a few days. That this physician left the city and was not available upon call from the patient and that the patient then called two other physicians, one of whom continued to take care of the patient for several weeks, at the end of which time the plaintiff's condition growing worse, a surgeon was called in consultation. About three weeks thereafter the surgeon performed a left ovariectomy. That after the performance of this operation the plaintiff remained in poor health and suffered pain for several months, during which time she was confined to the hospital or to her bed at home. She claims that this condition was brought about by the improper treatment of the physician originally consulted and the gynecologist, and sought to recover damages for her alleged injury. An action was also instituted on behalf of the husband to recover for the loss of his wife's services and moneys expended by him for medical care.

In about the middle of February the patient, accompanied by her husband, who was her second one, to whom she had been married about a year, consulted the defendant physician with respect to her not becoming pregnant. She also complained of a leucorrhoeal discharge. On a vaginal examination it was found that the uterus was swollen and soft, there being a large amount of leucorrhoeal discharge. A general physical examination was negative. After the examination the defendant physician advised that her con-

dition might be relieved in one of two ways, either by the application of violet ray or the performance of a curettage. The patient submitted to the application of violet ray, and over a period of about six weeks eleven applications were made. At the termination of this treatment the patient had left the city and was gone for some time. Upon her return she again consulted the defendant physician, and as her condition of which she complained had not improved, she then consented to the performance of a curettage. The attending physician advised the patient that he would administer the anesthesia and that a certain named gynecologist would perform the operation, to which the patient and her husband consented. The proper pre-operative instructions were given to the patient, and at the time arranged the defendant physician, accompanied by the gynecologist at the home of the patient, the husband being present, administered the general anesthesia of chloroform to the patient. The gynecologist then made a vaginal examination by means of a speculum and found the uterus soft and swollen and a profuse leucorrhoeal discharge. A smear examination of the discharge showed a resemblance to gonococcus which, however, was not definite. Upon dilatation the uterus was found to be soft, swollen and tender, the gynecologist stated to the defendant physician that the curettage could not be performed and all that was done at that time was to paint the surface of the uterus with iodine. Both physicians stayed with the patient until she had fully come out of the anesthesia. The husband being present at that time, they were both advised that the patient should remain in bed for several days, and should then come to the office of the gynecologist for further treatment. The defendant advised the patient that he was about to leave the city and would be gone for several days and would see her upon his return. That in the meantime, if necessary, she should call the gynecologist, giving to the patient his name, address and telephone. Several days later, on his return from out of town the defendant called upon the patient and was then advised by the patient that they had called in another physician and that his services were no longer needed. This was the last that he attended or treated the patient. He subsequently, however, treated the husband.

The defendant not being paid for his services made various attempts to collect the amount that was due him but was met with these suits of alleged malpractice. The actions not having been begun within two years after the cause of action accrued, upon our motion the complaints were dismissed on the ground that the actions were barred by the Statute of Limitations.

# LEGISLATION

By JAMES N VANDER VEER, M.D.  
Chairman, Committee on Legislation

## SUMMARY OF BILLS INTRODUCED IN LEGISLATURE IN SENATE

### Prohibition Enforcement

Senate Int No 29 (conc Assembly Int 527)  
—Assembly bill passed, but lost in Senate Codes Committee

### The Narcotic Bill

Senate Int No 115 (conc Assembly Int 215)  
—Senate bill passed, but died in Assembly Committee on Public Health

### Requiring the Licensing of Private Institutions for the Treatment of Drug Addicts

Senate Int No 116 (conc Assembly Int 216)  
—Died in committee in both houses

### The State Department of Education Bill Amending the Medical Practice Act

Senate Int No 211 (conc Assembly Int. 307)  
—Senate bill did not get out of committee  
Assembly bill 307 passed Assembly by a vote of 107 for to 37 against, but after being reported out in Senate, was recommitted to General Orders Committee, from which it could not be rescued

### Inspection by State Charities Boards of Children's Institutions

Senate Int No 228 (conc Assembly Int 236)  
—Died in committee

### Qualifications of Examiners in Lunacy

Senate Int No 263—Died in committee

### Lawful Orders of Local Health Boards or Officers

Senate Int No 278 (conc Assembly Int 414)  
—Died in committee

### Lawful Orders of Local Health Boards or Officers

Senate Int No 282 (conc Assembly Int 413)  
—Died in committee

### County Public Health Nurses

Senate Int No 283 (conc Assembly Int. 399)  
—Amended bill passed both houses, now in the hands of the Governor

### Health Service in Schools

Senate Int No 302 (conc Assembly Int 748)  
—Senate bill passed, but died in Assembly Public Education Committee

### Women's Compensation Law, in re Fibroid Phthisis

Senate Int No 308 (conc Assembly Int 386)  
—Bill passed both Houses, now in hands of Governor

### Relative to Powers and Duties of Local Health Boards

Senate Int No 349—Bill passed Senate, but died in Assembly Public Health Committee

### Vaccine Virus

Senate Int No 351 (conc Assembly Int 536)  
—Bill passed both Houses, now in hands of Governor

### Injured Employee to Select His Physician

Senate Int No 380 (conc Assembly Int 570)  
—Died in committee

### The Drugless Practitioner Bill

(By Gibbs)

Senate Int No 473—Reported on March 26th, but was not brought up for action

### Providing for Cleanliness in Shellfish Industry

Senate Int No 530 (conc Assembly Int 756)  
—Assembly bill lost, Senate bill died in committee

### Inspection of School Children

Senate Int No 586 (conc Assembly Int 850)  
—Bill passed both houses, now in hands of Governor

### Free Choice of Physician

Senate Int No 594 (conc Assembly Int 301)  
—Died in committee

### Practical Tests of Injured Persons

Senate Int No 647 (conc Assembly Int. 184)  
—Died in committee

### Physically Handicapped Persons

Senate Int No 671 (conc Assembly Int 868)  
—Bill passed both Houses, now in hands of Governor

### Dissecting Material

Senate Int No 681 (conc Assembly Int. 986)  
—Bill passed both Houses, now in hands of Governor

**Admission of Foreign Practitioners**

Senate Int No 693 (conc Assembly Int 950)  
—Died in committee

**In Relation to Pharmacies**

Senate Int No 632 (conc Assembly Int 802)  
—Died in committee

**Revocation of License to Practice Medicine**

Senate Int No 701—Died in committee

**Rural Hygiene**

Senate Int No 716 (conc Assembly Int 969)  
—Died in committee

**Hospital for Crippled Children at West Haverstraw, N Y**

Senate Int No 786 (conc Assembly Int 1074)—Died in committee

**State Institute for Study of Malignant Diseases**

Senate Int. No 787 (conc Assembly Int 973)  
—Died in committee

**The Bouton Chiropractic Bill**

Senate Int No 789—Died in committee

**Dissecting Material**

(Relative to delivery of cadavers to medical colleges)

Senate Int No 851 (conc Assembly Int 1027)—Bill passed both Houses, now in hands of Governor

**Laboratory Supplies**

Senate Int No 943 (conc Assembly Int 1167)—Died in committee

**A Chiropractic Bill**

(By Fearon)

Senate Int No 944 (conc Assembly Int 1423)—The Senate bill remained in committee. The concurrent Jenks bill in the Assembly was lost on March 25th by a vote of 85 to 50

**Foreign Licenses**

Senate Int No 1123 (conc Assembly Int 1478)—Bill passed both Houses, now in hands of Governor

**Censors State Medical Society**

Senate Int No 1176 (conc Assembly Int 1348)—Bill passed both Houses, now in hands of Governor

**Empowering Courts to Commit Drug Addicts to a City Hospital**

Senate Int No 1378—Bill passed both Houses, now in hands of Governor

In accordance with request received from Erie County Medical Society, your Committee on Legislation has filed objection to this bill

**Statement for Marriage Licenses**

Senate Int No 1412—Died in committee

**Bill in Opposition to Birth Control**

Senate Int. 1453—A bill introduced March 23rd, by Senator Thomas Burchill, of New York, would add new section 83, Penal Law, making it a misdemeanor to administer any drug or medicine or give any treatment to a woman for purpose of preventing conception, or to advertise to give such drug or treatment. Referred to Codes Committee

Died in committee

**IN ASSEMBLY****Health Service in Schools**

Assembly Int No 127—Died in committee

**Practical Tests of Injured Persons**

Assembly Int No 184 (conc. Senate Int 647)  
—Died in committee

**Nicoll Chiropractic Bill**

Senate Int No 185—Died in committee

**The Narcotic Bill**

Assembly Int No 215 (conc. Senate Int 115)  
—Senate bill passed, but died in Assembly Public Health Committee

**Institutions for Addicts**

Assembly Int No 216 (conc Senate Int 116)  
—Died in committee

**Mentally Retarded Children**

Assembly Int No 229—Died in committee

**Children's Institutions**

Assembly Int No 236 (conc Senate Int 228)  
—Died in committee.

**Free Choice of Physician**

Assembly Int No 301 (conc. Senate Int 594)  
—Died in committee.

**The State Department of Education Bill Amending the Medical Practice Act**

Assembly Int No 307 (conc Senate Int 211)  
—The Dunmore bill passed Assembly March 25th, by a vote of 107 to 37, but died in Senate Committee on General Orders

**County Public Health Notices**

Assembly Int No 399 (conc Senate Int 283)  
—Bill passed both Houses, now in hands of Governor

**Disclosure of Confidential Communications**

Assembly Int No 422—Died in committee

**Prohibition Enforcement**

Assembly Int No 527 (conc Senate Int 29)  
—Assembly bill passed, but lost in Senate Codes Committee

**Providing for Removal to Hospitals of Prisoners  
Requiring Medical or Surgical Treatment**

Assembly Int No 434—Bill passed both Houses, now in hands of Governor

**Free Choice of Physician**

Assembly Int No 570 (conc Senate Int 380)  
—Died in committee

**Chiropractic Bill  
(By Mr Esmond)**

Assembly Int No 649—Bill recommitted on March 25th

**Periodic Health Examination of Food Handlers**

Assembly Int No 678—Died in committee

**Health Service in Schools**

Assembly Int No 748 (conc Senate Int 302)  
—Senate bill passed, but died in Assembly Public Education Committee

**Medical Inspection in Schools**

Assembly Int No 850 (conc Senate Int 586)  
—Died in committee

**Regulating Sale of Wood or Methanol Alcohol**

Assembly Int No 908—Bill lost

**Reciprocity in Licensure**

Assembly Int No 925—Died in committee

**Rural Hygiene**

Assembly Int No 969 (conc Senate Int 716)  
—Died in committee

**The Birth Control Bill**

Assembly Int No 987—Died in committee

**Another Esmond Chiropractic Bill**

Assembly Int No 1343—Died in committee

**Medical Treatment of Injured Employees**

Assembly Int No 1351—Died in committee

**Scientific Experiments on Dogs**

Assembly Int No 1377—Died in committee

**Practice of Chiropody and Podiatry**

Assembly Int No 1421—Died in committee

**Chiropractic Bill  
(By Jenks)**

Assembly Int No 1423 (conc Senate Int 944)—Lost on March 25th, by vote of 85 to 50

**Sale of Eyeglasses and Lenses**

Assembly Int No 1429—Died in committee

**Chiropractic Bill  
(By Bolton)**

Assembly Int No 1463—Died in committee

**Practice of Pharmacy**

Assembly Int No 1539 (conc Senate Int 1231)—Passed both Houses, now in hands of Governor

# State Department of Health

## STATE HEALTH DEPARTMENT CONFERENCE

Forty-four members of the staff of the State Health Department, including the district state health officers, attended a conference at the Albany office on March 3d and 4th. Several matters of interest to physicians were discussed.

The Legislature being in session, considerable attention was given to pending health legislation. The district officers unanimously endorsed the Karle bill, increasing the compensation of local health officers and providing for the appointment of temporary acting health officers, a bill introduced at the request of the Department. They also favored requesting that the Webb-Lattin measure relating to the supervision of county nurses, a bill introduced at the request of the Department and the State Charities Aid Association, be amended in accordance with a suggestion of the Legislative Committee of the State Medical Society.

Dr. Ruth Gilbert, of the Division of Laboratories and Research, reported that during 1924 the following county laboratories had received state aid in accordance with provisions of Chapter 638, Laws of 1923: Montgomery, \$7,500, Ontario, \$3,000, Warren, \$3,700, Madison, \$2,325, Saratoga, \$4,200, Wyoming, \$3,100. It was stated that there had been marked development in three laboratories following the granting of state aid.

Dr. Branham, psychiatrist for the State Commission for Mental Defectives, outlined the plan which the commission is following in holding mental clinics for children in various localities, and requested the assistance of the district officers in getting children found to be in need of medical attention into the hands of physicians. He said that a limited appropriation and small staff made it difficult to make necessary contacts with local physicians.

In the forenoon of the second day the conference which was devoted to discussion of communicable diseases, was held in the auditorium of the City Hall, a number of health officers and other physicians from Albany and vicinity attending by invitation to hear a talk by Dr. William H. Park on the Dick test, immunization and serum treatment in scarlet fever.

Dr. Godfrey predicted for the coming year a low incidence of measles, with relatively high mortality if outbreaks occurred in children's institutions. He said that measles outbreaks in children's institutions were often reported too late to permit the use of serum as a preventative, and called attention to the fact that the serum might be effective if the ordinary precautions as to isolation were neglected.

In discussion of smallpox and vaccination it was brought out that the technique used in vaccination was at times open to serious criticism. It was suggested that, upon the occurrence of smallpox cases, the local physicians should always be gotten together if possible for discussion and demonstration of approved methods of vaccination. It was the consensus of opinion that the best dressing was a piece of sterile gauze strapped loosely to the arm with two strips of adhesive plaster, although some felt that no dressing was necessary in the first few days, if the vaccinated area was allowed to dry. It was agreed that the use of a bandage was inadvisable.

District officers reported that vaccination shields were still being used to some extent, describing several cases recently observed in which, upon removal of shields, collections of moist detritus and areas of hyperemia had been found. They recommended to the Public Health Council that it consider enacting a regulation prohibiting the sale of vaccination shields.

## UNCOOKED PORK APPARENTLY CAUSES THREE DEATHS IN TWO FAMILIES

According to a report recently received from Dr. H. J. Ball, district state health officer, three deaths occurred in two Indian families living in his district, the cause of which was apparently the eating of raw pork. A pig belonging to one of these families was killed about January 19. Six members of the family ate of this uncooked meat and became ill, and one of them, a child aged ten years, died February 16. On February 14 some of this meat was procured by a neighboring family and eaten raw by four children in the family. Two days later two of these children developed symptoms of gastroenteritis and one of

them died on February 19, the other on February 22. The other two children were not taken sick until February 21 and February 24. The former of these had a rise of temperature to 103 degrees and suffered with abdominal pain, vomiting, and aching in arms and legs. The latter complained of pain in the abdomen and legs. There were five other children in the second family who did not eat of the pork and who did not become ill.

The cases were brought to the attention of the district state health officer so late that a diagnosis was impossible.

## ANNUAL MEETING

### SUMMARY OF SCHEDULE

*House of Delegates, Monday afternoon and evening, and Tuesday morning Section meetings, Tuesday afternoon and Wednesday morning and afternoon Tuberculosis demonstration all day Thursday Annual Dinner, Tuesday Evening General Meeting, Wednesday evening*

### HOUSE OF DELEGATES

The regular annual meeting of the House of Delegates of the Medical Society of the State of New York will be held on Monday Afternoon, May 11, 1925, in the Ballroom of the Hotel Syracuse, Syracuse, N. Y.

OWEN E. JONES, M.D., *President*

E. ELIOT HARRIS, M.D., *Speaker*

EDWARD LIVINGSTON HUNT, M.D., *Secretary*

### 119TH ANNUAL MEETING

The regular annual meeting of the Medical Society of the State of New York will be held on Wednesday Evening, May 13, in the Ballroom of the Hotel Syracuse, Syracuse, N. Y.

OWEN E. JONES, M.D., *President*

EDWARD LIVINGSTON HUNT, M.D., *Secretary*

### PROGRAM

Calling the Society to order by the President, Owen E. Jones, M.D.

Address of Welcome by the Chairman of the Committee on Arrangements, Frederick H. Flaherty, M.D.

Reading of the minutes of the 118th Annual Meeting by the Secretary, Edward Livingston Hunt, M.D.

President's Address, Owen E. Jones, M.D.

Address, George E. Vincent, Ph.D., President, Rockefeller Foundation, New York City

### SPECIAL TUBERCULOSIS DEMONSTRATION

The committee on scientific work of the Medical Society of the State of New York has arranged a special day, Thursday, May 14 for a demonstration of Tuberculosis and all its varied phases. The special committee of which Dr. Edward R. Baldwin of Saranac Lake is chairman, has secured the co-operation of the outstanding specialists in tuberculosis of this country for this meeting. It has been planned that any physician will be able to obtain any information on any phase of tuberculosis. There has never been a meeting in this country in which this subject has been so completely covered as it will be on this occasion.

For program, see page 586

### ANNUAL BANQUET

The Annual Banquet will be held in the Hotel Syracuse Tuesday evening May 12th. Chancellor Flint of Syracuse University as well as other prominent speakers will be present.

### SECTION PROGRAMS

#### SECTION ON MEDICINE

Chairman—ROBERT L. LEVY, M.D., New York City

Secretary—L. WHITTINGTON GORHAM, M.D., Albany

It was suggested that, upon the occurrence of smallpox cases, the local physicians should always be gotten together if possible for discussion and demonstration of approved methods of vaccination. It was the consensus of opinion that the best dressing was a piece of sterile gauze strapped loosely to the arm with two strips of adhesive plaster, although some felt that no dressing was necessary in the first few days, if the vaccinated area was allowed to dry. It was agreed that the use of a bandage was inadvisable.

District officers reported that vaccination shields were still being used to some extent, describing several cases recently observed in which, upon removal of shields, collections of moist detritus and areas of hyperemia had been found. They recommended to the Public Health Council that it consider enacting a regulation prohibiting the sale of vaccination shields.

## UNCOOKED PORK APPARENTLY CAUSES THREE DEATHS IN TWO FAMILIES

According to a report recently received from Dr. H. J. Ball, district state health officer, three deaths occurred in two Indian families living in his district, the cause of which was apparently the eating of raw pork. A pig belonging to one of these families was killed about January 19. Six members of the family ate of this uncooked meat and became ill, and one of them, a child aged ten years, died February 16. On February 14 some of this meat was procured by a neighboring family and eaten raw by four children in the family. Two days later two of these children developed symptoms of gastroenteritis and one of

them died on February 19, the other on February 22. The other two children were not taken sick until February 21 and February 24. The former of these had a rise of temperature to 103 degrees and suffered with abdominal pain, vomiting, and aching in arms and legs. The latter complained of pain in the abdomen and legs. There were five other children in the second family who did not eat of the pork and who did not become ill.

The cases were brought to the attention of the district state health officer so late that a diagnosis was impossible.

## SECTION ON EYE, EAR, NOSE AND THROAT

Chairman—ARTHUR G BENNETT, M D, Buffalo  
Secretary—EUGENE E. HINMAN, M D, Albany  
Place of Meeting—Hotel Syracuse

## TEACHING CLINICS IN PEDIATRICS

A series of five teaching clinics in pediatrics has been planned to be given in the South Side Hospital, Bay Shore, Long Island on Tuesday afternoons, beginning on March 31st, under the auspices of the Suffolk County Medical Society. They will be a part of the graduate education scheme of the Joint Committee on Graduate Education of the Medical Society of the County of Kings and the Long Island College Hospital Medical School. The plan is sponsored by the Second District Branch Medical Society of the State of New York and the Associated Physicians of Long Island, and is largely the result of conferences among the officers of the two societies.

The organization which will have charge of the actual operation of the clinics is the South Side Clinical Society, which is a group composed of the members of the Suffolk County Medical Society who live in the southwest corner of the county and compose the staff of the South Side Hospital. While all the plans have not been perfected, it is expected that the State Department of Health will lend its assistance.

The clinics which have already been announced are as follows:

March 31st—Simplified Infant Feeding, Dr. Frank H. Richardson, representing the Brooklyn Pediatric Society.

April 7th—Malnutrition, Dr. Charles Hendee Smith, of Bellevue.

April 14th—Prenatal Care, Dr. John O. Polak, of the Long Island College Hospital.

April 21st—General Pediatrics, Dr. Royal Storrs Haynes, of Sloane Maternity Hospital.

April 28th—Tonsils and Adenoids, Dr. Albert D. Kaiser, of Rochester.

It is expected that the local physicians will supply cases for demonstration, and that the teachings will be the discussion of the cases.

These clinics have been carefully planned and could readily be adapted to the needs of other parts of New York State. The request for the clinics came spontaneously by the unanimous vote of the members of the South Side Clinical Society, twenty-two of whom were present at a meeting on March 18th, at which the plan was considered. The promoters of the series feel that the clinics will be a practical demonstration which will result in requests for similar clinics held under the auspices of the district branches and county medical societies in other parts of New York State. Suffolk County is as rural as the counties around Syracuse, Rochester, Binghamton, and other up-State cities, and the teaching facilities of those cities are as available as those of Brooklyn.

A great merit of the Suffolk County plan is that it can be put into operation wherever a group of physicians will voluntarily ask for the clinics. Suffolk County happens to be favorably organized to support such a series of clinics, because there is a general hospital in each of the four corners of the county, each with an organized staff. But similar groups who desire teaching in any line of medicine could be readily organized in any county.

discussions will be limited to 3 minutes

## DINNER TO PHYSICIANS WHO HAVE PRACTICED MEDICINE MORE THAN FIFTY YEARS

The committee of the Albany County Medical Society to arrange for a dinner for those members of the Society who have practiced medicine for fifty years or more report splendid progress in their plans

The Albany County Medical Society has the unusual honor of having in its membership eleven physicians who have actually practiced medicine for more than fifty years, among them, three who are ex-presidents of the Medical Society of the State of New York and several who have national reputation in medicine. Albert Vander Veer, Cyrus S. Merrill, Frederic C. Curtis, James P. Boyd and Herman Bedell are outstanding personalities.

It is planned to give this dinner at the Fort

Orange Club, on Wednesday, April 29th, in recognition of the worth and work of these, our associates.

The committee of arrangements believe that on such an occasion, unique in the annals of the Medical profession in any section of the United States, it would be fitting to honor these men in a manner which would do justice to their reputation and reflect credit on the members of the Society.

The Rockland County Medical Society is planning a dinner in honor of Dr. William R. Sitler, of Suffern, who graduated from the University of Pennsylvania fifty years ago, and is still in active practice, both as a family physician and as health officer.

## NEW YORK STATE SOCIETY OF INDUSTRIAL MEDICINE

The New York State Society of Industrial Medicine will hold its semi-annual meeting at the Ten Eyck Hotel, Albany, N. Y., on April 16th.

The meeting will be opened at 10 A. M. with a brief address of welcome by the Hon. W. S. Hackett, Mayor of Albany.

The scientific program will follow immediately and continue through the day. The speakers and their subjects are as follows:

"Disabilities of the Hand," H. H. Lyle, M. D., New York City.

"Injuries of the Genito-Urinary Tract," James Vander Veer, M. D., Albany.

"A Critical Study of Some Factors Influencing Recovery in Accident Cases," E. MacD. Stanton, M. D., Schenectady.

Discussion of each address will be opened by a well known specialist and followed by general discussion.

Noon recess and luncheon at the Ten Eyck Hotel from 12:30 to 2 P. M.

## THE PHYSICIANS' HOME BENEFIT

The Medical Profession of Greater New York and vicinity is advised of a method for securing support for The Physicians' Home and at the same time enjoying a popular opera at the Century Theatre.

"The Love Song" by Offenbach comprises a collection of musical productions by that author. The hero of the play represents Offenbach himself. It is one of the great successes of the season.

The Physicians' Home Committee has secured the Century Theatre for Monday, April 20th, and it offers tickets at agency prices.

Physicians who purchase two or more tickets for box seats, orchestra or dress circle will receive membership certificates for 1925 in The Physicians' Home. This organization takes

charge of physicians, who, through age or illness, require a helping hand. It gives them a pleasant home in the country as guests of the profession.

Tickets for the opera may be obtained by mail from the Secretary, Dr. Silas F. Hallock, 901 Lexington Avenue, New York. Those who send checks will receive tickets in reference to seats in the order of receipt of the checks. Please give us a prompt reply and please ask your friends in and out of the profession to enjoy this opera while at the same time lending a hand for a fine charity.

Box Seats, \$7.00  
Orchestra, front rows, \$7.00, back rows, \$6.00  
Dress Circle, front rows, \$6.00, back rows, \$5.00  
Balcony front rows, \$2.50 and \$2.00, back rows, \$1.50  
Second Balcony, \$1.00

## OPPORTUNITIES FOR GRADUATE MEDICAL STUDY IN NEW YORK

The Committee on Medical Education of The New York Academy of Medicine has prepared a series of synopses of approved opportunities for graduate medical study in New York City which will soon be published for distribution. The synopses cover dermatology and syphilology, obstetrics and gynecology, internal medicine, neurology and psychiatry, ophthalmology, otolaryngology, pediatrics, surgery, urology, and orthopedic surgery.

A Bureau of Clinical Information is maintained at the Academy of Medicine, 17 West 43rd Street, where detailed information is available regarding opportunities for graduate medical study in New York, and also in other cities of the United States and abroad. The Executive Secre-

tary in charge of the Bureau is prepared to answer inquiries concerning ordinary internships, special internships or residencies, graduate courses in medical schools and teaching hospitals, and extension courses. Much information in regard to graduate medical work in England and on the Continent is on file.

The Bureau publishes a Daily Bulletin of Surgical Clinics which will be mailed free to visiting doctors on request. A Weekly Bulletin of Medical Clinics also is published. A book of fixed clinics of Greater New York, with a transportation guide, has been prepared for the use of visitors whose stay in the City is limited, and is furnished without charge.

## SPECIAL MESSAGE OF GOVERNOR SMITH

State Department of Health  
Albany, N. Y., March 28, 1925

MY DEAR EDITOR

Now that the annual battle to uphold the Medical Practice Act is over and in spite of the defeat of the Karle-Dunmore bill, it seems to me that certain definite facts have come to light which have made the losing fight worth while.

1st That the medical profession of the State is better organized than ever before in the history of the State and is making such organization felt not only in the legislature but throughout the State.

2nd And to my mind most important of all, for the first time there has been placed on the written and spoken record the fact that the chiropractic and other cults claim the right by their various peculiar methods to treat infectious diseases and resent any interference by law with that right. This fact should be spread broadcast throughout the State.

May I take this opportunity to testify to the earnest and effectual work of Dr. Joseph Lawrence, representing the State Medical Society, and on the last day of the session of the legislature to that of Dr. Booth of Elmira?

I enclose a copy of the Governor's message to the legislature, of which the press this morning gave but casual mention. I think it is worthy of record as showing the Governor's attitude toward the Medical Practice Act.

MATTHIAS NICOLL, JR.,  
*Commissioner of Health*

State of New York, Executive Chamber  
Albany, March 27, 1925

TO THE SENATE

You have on the calendar in the Senate, Assembly Bill, 1854, entitled "An Act to amend the public health law, in relation to the practice of medicine." It has passed the Assembly by an overwhelmingly majority. It is in line with the recommendations that I have heretofore made to the effect that the State must be more vigorous in the prosecution for violation of the Medical Practice Act.

The bill seeks to give the State a control over the practice of medicine, which it is agreed by the State Department of Education, the State Department of Health, and more than ten thousand practicing physicians of the State we should have. I can think of no function in the government as important as the preservation of public health. The unlawful and illegal practice of medicine is a crime against the people and to permit it to go unpunished or even undetected bespeaks a failure on the part of the State to properly strengthen the arm of one of our greatest departments of government. It is inconceivable that there could be abroad in the State any influence seeking to stay the hands of public authority in the prevention of the illegal practice of medicine.

I earnestly hope that before you adjourn this bill will receive your most careful consideration.

(Signed) ALFRED E. SMITH

## REPORT OF COMMITTEE ON NURSE QUESTION

### To the President and Members of the Society

After careful consideration of the various factors entering into the so-called nurse situation as it exists today in Erie County, and throughout the State of New York as well, your Committee desires to submit this report, covering the following points

1 What, if any, are the just grounds for criticism of the present status of the registered nurse with relation to the public and to the physician?

2 What are the underlying causes of the unsatisfactory conditions that we find not only evident but increasingly prevalent?

3 What definite remedies can we recommend to relieve the situation?

### I—GROUNDS FOR CRITICISM

1 *Scarcity of Nurses* Evidence of the claim that there are insufficient nurses to supply the demands of the sick public is presented so frequently both by physicians and laymen requiring nursing service as to thoroughly substantiate the claim in the minds of the Committee. This more or less constant shortage becomes acute during epidemics or seasonal illness

2 *Nursing in Private Homes* Testimony of physicians and laymen is abundant evidence of the increasing unwillingness of a large number of Registered Nurses to accept calls to nurse in private homes

3 *The Twelve-Hour Schedule* Your Committee realizes that there are valid arguments advanced on both sides of the question of limiting the nurse's time on duty to twelve hours. Without entering into a discussion of the merits of this question your Committee is convinced that one result of this schedule is to work a great financial hardship on the sick public, the great majority of whom are unable to meet the expense involved.

Especially burdensome is this system on maternity patients. Your Committee believes that the great increase in expense for nursing in these cases tends to make it almost prohibitive for people of moderate means to accept parenthood, and so constitutes a serious menace to the birth rate among the very class in which a high birth rate is most desirable.

4 Your Committee finds evidence of an increasing tendency on the part of some Registered Nurses to exercise the functions of a physician rather than a nurse in their relations with patients. While we believe that this by no means holds as a criticism of any but a minority of nurses of today, we are impressed with the apparent growth of this attitude of mind on the part of many nurses

### II—UNDERLYING CAUSES OF CONDITIONS CRITICIZED

1 An increasingly large number of nurses are being drawn into special lines of work other than bedside care of the sick—such as Industrial dispensaries, public health nursing, institutional positions, etc.

2 Under the present system of training, emphasis is laid on the larger sphere of the professional woman. While your Committee would be the last to deprecate the expansion of any woman's sphere of usefulness, the practical fact remains that such aspirations on the part of nurses seem to result in a diminished enthusiasm for the performance of the real function of a nurse, viz, caring for the comfort of her patient and executing the orders of the physician.

3 The expanding curriculum further serves to educate nurses beyond the point of practical usefulness in their actual work, engendering in many the desire to exercise the function of one who treats the patient rather than one who cares for the ailing. In other words such nurses are not content, on the one hand, to play true rôles of the physician's representative on the case and, on the other hand, many of them are

misled into thinking that the general smattering of medical education which they receive renders them competent to practise medicine rather than nursing

4 The present high requirements as to preliminary education of a pupil nurse, viz., a high school course, together with a three years course of hospital training, makes for dissatisfaction with the financial returns on the investment of time and money necessary to secure such training

5 The preliminary high school course requirement serves to debar many young women of high character and ability such as formerly chose nursing as a calling from sheer love of the work. The number of applicants for training is thus greatly limited, with the resultant scarcity of women in the nursing ranks

### III—SUGGESTED REMEDIES

1 Your Committee's unhesitating recommends reducing the preliminary requirements of applicants for nurse training to a grammar school education—placing emphasis more on character, ability and enthusiasm of the applicant for this special field of work.

2 We would modify the curriculum in training schools so as to require two years of practical bedside training, limiting didactic instruction to the elements of anatomy, physiology, disease causation, modes of infection, practical asepsis, etc

3 We advocate granting a diploma at the end of the second year, graduating the pupil as a Qualified Nurse, with the privilege of registering and using the degree of R. Q. N.—Registered Qualified Nurse.

The idea of creating the class of Qualified Nurses is to clear the curriculum of useless advanced scientific specialties, to shorten the unnecessarily long period of training and to readjust the education to the necessities of medical and surgical practice.

4 We would arrange the curriculum for a third year of training for those who so elect—consisting of more advanced work in those studies necessary to prepare them for public health nursing, institutional work and other activities than actual bedside care of the sick. At the end of the third year, according to this plan, a diploma might be granted as Master Nurse, with the privilege of registering with the Regents and using the degree of R. M. N.—Registered Master Nurse.

To be eligible for this advanced degree the applicant must have had a High School Education. Her first two years of training would be the same as that of applicants for a diploma as Qualified Nurse, but her third year would be advanced technical, administrative or specialty courses, as the candidate for the degree might elect.

5 As a concrete suggestion of how this general plan might be carried out your committee submits the following tentative curriculum, giving in one column the hours now required in the various subjects taught, and in a second column the suggested changes to be made.

### SUGGESTED CHANGES IN NURSING SCHOOL CURRICULUM, WITH PRESENT PRESCRIBED HOURS

1st Semester	1st Year	
	Prescribed	Suggested
Anatomy and Physiology	48	36
Bacteriology	16	4
Personal Hygiene	8	6
Chemistry	16	4
Nutrition and Cookery	24	24
Hospital Housekeeping	8	8
Drugs and Solutions	16	6
Elementary Nursing	64	64
Historical, Ethical and Social Basis of Nursing		
Introduction to Private Nursing	8	3
	208 h. (12 h per week)	155 h. (Save 53 h (9 h per week)

### BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Hollywood Gardens, 896 Prospect Avenue, on March 18, 1925, was called to order at 8 45 P M, the President, Dr Jacobs, in the Chair

Isaac Astrachan, Morris Blum, Thomas Levin, Samuel Lessinger, Morris Henry Oken, Gordon D Oppenheimer, Jacob Segal, were elected to membership, and Frederic W Bancroft, associate membership

Dr Weiztner introduced the following resolutions

"WHEREAS, The Bronx County Medical Society has sustained a severe loss in the death of its honored associate, Chester C Curtis, M D

"*Resolved*, That the Bronx County Medical Society record the sense of its loss in the death of Dr Curtis and that a minute thereof be placed on the records of the Society, and be it

"*Further Resolved*, That a copy of these resolutions be transmitted to the family of our departed member"

These resolutions were carried by a rising vote

Dr Podvin, who had been appointed by the President to represent the Society at the conference called by the Bronx Board of Trade, reported that a mass meeting will be held on March 27th, at Morris High School, when the future welfare of Bronx borough will be discussed

The President, Dr Jacobs, announced with regret the resignation of Dr Eichler as Chairman of The Bulletin Committee Dr Eichler has found it impossible to devote the time necessary for the proper performance of this work and has asked to be relieved The President further announced that he had appointed Dr Edward C Podvin as Dr Eichler's successor Dr Podvin appealed to the members for their cooperation

The Scientific Program then proceeded as follows

#### PRESENTATION OF CASE

"Carcinoma of Testicle Following Trauma (ten years post-operative)," J Lewis Amster

#### PAPERS

1 "Prevention of Cancer," James Ewing

2 "Essentials in the Diagnosis and Cure of Cancer," Herbert M Bergamini

3 "Practical Results of the Campaign Against Cancer," George A Soper, Ph D

Discussion by Drs William Stone, Burton J Lee, Isaac Levin, Henry Roth, J Lewis Amster and Adolph Rostenberg

Dr Podvin moved that a vote of thanks be extended to the readers of the papers of the evening This motion was unanimously carried

The meeting adjourned at 11 30 P M

I J LANDSMAN, *Secretary*

### CORTLAND COUNTY MEDICAL SOCIETY

The regular quarterly meeting of the Cortland County Medical Society was held at the High School Building, in the City of Cortland, on Friday, March 20, 1925

Professor Flora Rose, of Cornell, gave an interesting talk on food selections for infants and children

Dr Frank Howard Richardson, of Brooklyn, addressed the meeting on the subject of breast feeding

These papers were discussed by the members of the society

The society then took up the business of the evening, and upon receiving the report of the Censors voted to elect to membership in the society Dr Albert A Bailey, of Cortland, and Dr Hugh Frail, of Marathon

The meeting was then adjourned

A M LOOPE, *Secretary*

### MEDICAL SOCIETY OF THE COUNTY OF ERIE

#### REGULAR MEETING, MARCH 16, 1925

*Resolved*, That the Report of the Committee on Nurse Question which has been submitted to the Society at this meeting be adopted

*Resolved*, That the Committee be authorized to have said Report printed and a copy of same mailed to each member of the House of Delegates for the coming year Also a copy to every hospital in the State of New York Also a copy to a list of physicians and surgeons connected with various hospitals throughout the State, such list to be chosen by the Committee Also a copy to every member of this society (*See next page*)

*Resolved*, That the Delegates of this Society to the State Society be and hereby are instructed to use every effort to secure action by the next House of Delegates looking toward the introduction by the State Legislative Committee of a Bill embodying these or similar ideas regarding the training of nurses

*Resolved*, That the Delegates be also instructed to work for the establishing in the State Society of a Standing Committee on Nurse Training, whose duty it shall be to advise with the State Legislative Committee on all proposed legislation touching this question

periodic health examinations The medical profession, he said, has been so busy looking after the sick that it has had very little time to spend on prevention and general health Infant mortality in the State has been greatly reduced in the last ten years and Dr Jones is confident that equal results can be accomplished with adults by periodic health examinations

Dr William A Hagan, Professor of Bacteriology of the Cornell Veterinary College, gave a short but very instructive address on "Tularemia" which appears to be spreading over the country from the West The infection is an attenuated form of the once terrible bubonic plague, and is carried by rodents, particularly ground squirrels and rabbits

Recent investigation has shown its organism to have great infectivity, a single drop on the skin of a guinea-pig, without abrasion, will produce the disease It is highly communicable to man and produces a sickness of about three weeks and a slow convalescence extending over several weeks

Practically every laboratory worker who has handled the organism has been infected The disease is said to have been recently detected in the Adirondac region

Livingston Farrand, M D, President of Cornell University and member of the Tompkins County Medical Society, dealt with topics relating to the pending Medical Practice Act Among other things, he said, "One of the great prob-

lems confronting the medical profession is a conception of its responsibilities There is a tendency to aim for particular personal or group prestige and interest The surest way to attain prestige and success is to forget personal or group interest The interest of the community is the interest of the group The demand for the medical profession is greater today than it ever was The day is coming when the medical profession must take the initiative, with a judgment not primarily concerned with what the particular interests of the group may be

We have seen an immense improvement in the realization by the medical profession of its responsibility to lead and guide in this movement of public enlightenment The broadest possible point of view must be taken by physicians I am optimistic with regard to the future of the medical profession and its educational functions After all, the public health and vitality is what we are driving at

There is no symptom of a lessening demand for a highly trained medical profession On the contrary, there is every evidence of a constantly increased demand, which the world must see realized "

The program of the evening was interspersed with stunts and varied entertainment by members of the Savage Club and students of the Ithaca Conservatory of Music.

WILBER G FISH, *Secretary*

---

## GORGAS MEMORIAL

Perhaps one of the most interesting recent developments in the plans of the Gorgas Memorial Institute of Tropical Research and Preventive Medicine, a co-operative movement for better health, controlled by the medical profession, but actively backed by eminent lay members, is the widespread enthusiasm for, and cordial reception accorded Gorgas Memorial radio talks These are now being given in all the principal cities, notably over station WOR, Buffalo, and through the courtesy of the New York Health Speakers' Service, over WEAJ in New York

A Speakers' Bureau is now being organized from among the New York State Governing Committee members In brief, judging from the many letters received and other evidences of public response to these broadcasted Gorgas Memorial addresses, there is no question in the mind of those responsible for the Gorgas Memorial as to the need for authoritative health information directed to the "man on the street" through the channels to which he is accustomed, viz the daily newspaper, the general magazine, the radio, lectures from the platform and by moving picture films

On March 20th at 7 P M over WEAJ Dr George David Stewart, happily launched the radio program of the Gorgas Memorial for New York City Wednesday morning, March 25th, Dr William Francis Honan spoke for the Gorgas Memorial on "The Child's Best Heritage," this being the first radio address of a series planned by WEAJ to interest young mothers Subsequent addresses of this series are to be given every Wednesday morning at 11 10 over WEAJ by members of the Gorgas Memorial Speakers' Bureau Among the speakers scheduled are Dr Charles Mallory Williams, who will speak April 1st on the care of the infant with reference to skin disease and Dr Foster Kennedy, who is to present the cause of mental hygiene, April 22nd

We quote from Dr Stewart's radio presentation of the Gorgas Memorial

"Who was Gorgas and why is this institute named after him? William Crawford Gorgas began his professional life as a Lieutenant in the Medical Service of the United States Army He retired with the rank of Surgeon General, but between those periods he had served in Frontier Army Posts—had taken an eager scientific inter-

2nd Semester	Prescribed	Suggested

#### 3rd Year—Senior

(Two or three of the courses of the third year could be added to the second year to meet special conditions in training a Registered Qualified Nurse.)

The pupil wishing to take a third year leading to the

degree of Registered Master Nurse might be allowed an elective course, choosing her subjects from some such list as the following, according to her individual leaning toward some special line of work.

- 1 Nervous and Mental Diseases
- 2 Occupational Therapy
- 3 Administration Problems
- 4 Laboratory Technique.
- 5 Anaesthesia
- 6 Modern Social Conditions
- 7 Field Work, Social Service Work, Public Welfare Work.
- 8 Tuberculosis Nursing
- 9 Nursing Mentally Defective Children
- 10 Gynecological Nursing
- 11 Obstetrical Nursing
- 12 Psychology, etc.

Finally, your committee wishes to disclaim any idea of personal criticism of any or all Registered Nurses now practising their noble profession. The criticisms herein contained are directed only at the present system of nurse-training, for which ill-judged system no responsibility or blame can attach to those who have been trained under its administration.

The whole matter can be reduced to very simple terms *What is the aim of nurse training?* Is it to train nurses, as the term implies,—that is, women whose first and chief mission is to care for the man woman or child who is sick and in need of her care? Or is the aim to impart in a most superficial manner a quasi medical education which is utterly insufficient to qualify its recipient for medical practice, but serves only to weary their brains with a mass of undigested medical facts?

Should not nurse-training strive mainly to develop the pupil's powers of intelligent observation, to inculcate a sense of responsibility for the execution of the physician's orders, and, last but not least, develop to the highest degree her skill in ministering to the sick?

Your committee believes that it should.

Respectfully submitted,

COMMITTEE ON NURSE QUESTION  
 GEORGE R. CRITCHLOW, M.D.  
 THEW WRIGHT, M.D.,  
 IRVING M. SNOW, M.D.,  
 DEWITT H. SHERMAN, M.D.,  
 JAMES A. GARDNER, M.D.,  
 EARL P. LOTHROP, M.D.

## TOMPKINS COUNTY MEDICAL SOCIETY

The Annual Dinner of the Medical Society of the County of Tompkins was held Wednesday evening March 18, 1925, with members and guests present to the number of 110.

When professional men foregather for a function of this type, their professionalism is characteristically relegated to the background. If there had been any hesitancy in such relegation at this time the toastmaster would have completed it with dispatch. He was listed in the program as Dr Rym Berry (Romeyn Berry, Graduate Manager, Cornell Athletic Association). "Dr" Berry's sparkling repertoire and sprightly stories were typically Berry-esque.

President John W. Judd opened the post-prandial program by introducing Mr Berry, and by presenting a floral token of appreciation to Dr Esther E. Parker, past president of the society and the only active woman practitioner in Ithaca.

Dr Owen E. Jones of Rochester, President of the State Society was the first speaker. He referred to past and present activities of the society with emphasis upon the Medical Practice Bill now before the State Legislature.

He said, "The Legislature has passed bills regulating admission and practice in nearly all other professions, but today almost any cult can practice medicine with no legal qualifications whatever. This condition is unusually strange, in that the health of the community or State is its greatest asset." He urged the use of the combined influence of medical societies toward the passage of the Medical Practice Bill, which would provide limitations of admission to practice.

"The medical profession in itself," he continued, "is the group best qualified from every standpoint to look after the public health."

Dr Jones also advised the Tompkins County Medical Society to get behind the movement for

# THE DAILY PRESS

Is New York State threatened with a recurrence of influenza? The newspapers are beginning to take notice of an outbreak of the disease in Chicago. The *Brooklyn Citizen*, March 13th, contains a statement ascribed to Dr Herman Burleson, Health Commissioner of Chicago, which sums up the situation. The doctor is quoted as saying

"Eight deaths were reported to this office for the thirteen hours period ending at 10 P M yesterday making a total of 279 deaths from respiratory diseases since March 1"

The *Brooklyn Times*, March 15th, throws more light on the distribution of influenza cases, and says

"It is evident, that the disease is not confined to the city on the shores of Lake Michigan. In Springfield, Vt, where the population is only seventy-five hundred, the Health Officer reports five hundred suffering. Manchester, N H, reports that between fifteen hundred and two thousand people are suffering from influenza."

Dr Bundesen, in the article quoted above, gives some sensible advice regarding the prevention of influenza, and says

"The present epidemic should be easy to combat if the public would help. The malady is highly contagious and if the people who feel the symptoms would go to bed and keep away from contacts we could stop the epidemic very soon. But sufferers continue to get around, expectorating, spreading the germs, with the result that scores and scores of people are infected daily."

Dr Bundesen has issued a bulletin offering free anti-pneumonia serum from the city laboratories to physicians for the duration of the epidemic.

We have a clipping which has appeared in three papers, the *Poughkeepsie Star*, March 17th, the *Elmira Advertiser*, March 17th, and the *New York Bulletin*, March 20th, two of which were run as editorial comment. The clipping is as follows

"Health officials never yet have succeeded in stopping an epidemic of influenza. The avoidance of 'flu' or its consequences is a personal problem for each individual.

"This is the time of year to be particularly on guard against 'flu' and pneumonia—as the two always go together—for in most vicinities their ravages usually reach the maximum toward the close of winter.

"Cleanliness, good physical condition and plenty of sleep are our best safeguards. Some-

thing besides germs is usually required to make us sick. Much depends on our general condition—our 'resistance'."

We are quoting the clipping in order to call attention to a defect in the manner of its presentation in the three papers. Neither paper gives the author or gives any clue to the author of the clipping.

We also call attention to the point which the three clippings emphasize, and that is the "resistance" of the patient. There are three great factors which affect the spread of epidemic diseases

- 1 The virulence, or vitality, or growing qualities of the germs which produce the disease. Some varieties of influenza germs are weak, and have difficulty in growing in the body, and others are vigorous and will grow if they have half a chance.

- 2 The general vigor and healthfulness of the body. Fatigue, for example, has considerable effect in lessening the ability of the body to kill influenza germs.

- 3 The presence of antitoxins against influenza in the body. Most people do not have the antitoxins until they have had influenza.

There is no practical way to cause the body to produce antitoxins against influenza.

A person may be ever so vigorous and healthy, and yet if he is exposed to a case, he is likely to come down with influenza unless he has had the disease before.

The most promising method of attacking an epidemic of influenza is that of preventing the spread of the germs from those who have influenza or other form of "colds."

This cannot be done by law or compulsion. It must come through education.

The basic fact to teach the people is that the excretions of the nose and throat are as dangerous and require as careful disposal as those of the bowels and bladder.

The campaign for the disposal of all forms of sewage has been going on for half a century, and the lesson has now been learned so well that diarrhoeas and other forms of intestinal infections are uncommon, and their presence arouses immediate protest.

A campaign of educating the people regarding the disposal of the excretions of the nose and throat will take a generation of time.

Why not start the campaign now?

The *Troy Record*, March 20th, has a short

est in yellow fever While on duty at one of his posts he had passed safely through an attack of yellow fever and thus became immune He had banished yellow fever from Havana where he was backed by the Military and Civil authorities, had banished the same disease from the Panama Canal Zone and made possible the building of the Canal, saving the lives (based on the mortality records of the French Company) of 60,000 men and affecting an economic saving of \$80,000,000 In this undertaking he was backed by the authorities in only a half hearted way and several times he was on the point of being recalled but his patient persistence won through

"Then when the World War broke out, Surgeon General Gorgas was responsible for the health of four million men and he watched the Army Medical Corps, of which he was the head, grow until in numbers, it surpassed the entire standing army before the war After the war was ended and General Gorgas had retired under the age limitation, the English Government asked him to go to Africa because General Gorgas believed he could rid the world of yellow fever and he could have done so, but in London he fell ill and died His work was finished

#### "WHAT HAS BEEN DONE

"A great deal has been done as you know by Health Boards, by Foundations and other organizations to prevent diseases but a great deal remains to be done Out of each 100,000 of the population each year tuberculosis takes 97, a few years ago it took 200 Heart disease takes 150, pneumonia 140, nephritis or kidney disease takes 89 and apoplexy claims about 90

"About 87 per cent of all deaths are due to infection and if cancer is considered a bacterial disease then 97 per cent of all deaths will be due to infections

"When the call of troops was made to get four million men fit to serve it was necessary to call between six or seven million men and remember these were all young men Now it doesn't seem fair that 34 per cent of the men under 30 were found suffering from disease or the defects of deformities produced by disease and it is just this condition of affairs that the Gorgas Memorial Institute is attempting to correct. Every good movement must have a sign or symbol under which it functions and what better than the name of the unselfish, practical altruistic Gorgas

"WHAT IS THE IDEA OF THE GORGAS MEMORIAL

"The idea of the Gorgas Memorial Institute is three-fold

"1 It wants to create in Panama as a memorial to Gorgas an Institute or school for research into tropical medicine Think of the immense

areas that will be added to the world's resources by these studies

"2 To inaugurate a personal health educational campaign that will bring every individual in this country to his doctor once or, better, twice a year, no matter how healthy he may be, just to find out that there are no knocks in the engine that it is running smoothly and without friction.

"3 If the doctor has not all the equipment necessary to make this examination the institute proposes to furnish him with what he needs It won't be enough for your doctor to look at your tongue, take your pulse and thump your chest once or twice so it may be necessary for the institute to educate (here any doctors listening in may turn off the loud speaker) the doctors to go over the heart and lungs, the stomach, kidneys, arteries, blood, blood pressure, glands, eyes, ears, nose, throat, feet, mental pose, etc

"The doctors themselves are back of all this A Committee of 100 Doctors for every one million population and each of them has gone into his jeans for \$100 contribution Figure that out. There can be no selfish motive in it, can there—to help to keep well is not going to put anything into the doctors' pockets, is it? In fact, the doctors will give about \$600,000 To carry out this plan five million dollars is necessary, only the income of which is to be used, one-fifth of it to go to the school of Tropical Medicine in Panama, four-fifths to this personal health educational campaign

"This personal health campaign is absolutely necessary There is no machinery at present available for compelling people to be examined, so they must be taught the necessity and value of such examinations in order that once a year, twice is much better, they will come, voluntarily even, demanding an examination

"Just what old age means and whether or not you can and want to add to yours—you can only add to the end—may be a question with some of you The psalmist's allotment of three score and ten or possibly four score years is a lugubrious one and runs thus, 'The days of our years are three score years and ten and if by reason of strength they be four score yet is their strength labor and sorrow' Now that is not what we want—not to add labor and sorrow The sum of human life has already been lengthened in the last half century But another half dozen years, perhaps more and happy years, may be added in the next quarter or half century if you will only go to your doctors twice a year and insist on getting a certificate that the delicate machinery having been overhauled has been, or will be made all right. That is the aim of the Gorgas Memorial"

# BOOK REVIEWS

**ESSENTIALS OF PRESCRIPTION WRITING** By CARY EGGLESTON, M.D. Third Edition, revised. 146 pages Phila and London, W B Saunders Co, 1924 Cloth, \$1.50

In these days of intensive medicine when students and practitioners alike are so keenly interested in the rapid changes that are taking place in our knowledge of diseases, their causes, and treatment, the art of correct prescription writing seems to have been entirely neglected. The recent graduate, though properly instructed, seldom gives much time to this subject and the busy doctor likewise considers other things more important with the result that both are in a dilemma when prescribing and are at a loss to know how and in what way to prescribe so that their receipts are pharmaceutically, chemically and therapeutically accurate. In addition, little attention is given to grammatical construction. There are many books on this subject that are valuable but most are too voluminous to be practical. This present volume of Eggleston's, in its third edition, is concise and covers the essentials exceedingly well. The chapters on Latin grammar, grammatical construction or prescriptions, practical writing of prescriptions, vehicles, and incompatibility, are well worth reading. To those who wish to improve themselves in this art this little book will answer admirably.

FREDERICK SCHROEDER.

**THE ROMANCE OF A LIVING TEMPLE, A STUDY OF THE HUMAN BODY** By FREDERICK M. ROSSITER, B.S., M.D., L.C.R.P., M.R.C.S., London, Professor Medicine, College of Medical Evangelists, Los Angeles, Cal. George Sully & Co, New York, 1924

This is a most elementary treatise on human physiology. By the use of very simple language and well selected comparisons the author has succeeded in presenting his subject in a way that will insure the sustained interest of the young readers for whom the book has been written.

FRANK E. MAILLON.

**GUY PATIN, AND THE MEDICAL PROFESSION IN PARIS IN THE XVIIITH CENTURY** By FRANCIS R. PACKARD, M.D. Author of *Life and Times of Ambroise Pare*. Seventeen illustrations, nine full page plates. Paul Hoeber, Inc., New York, 1924. Price, \$4.00

Guy Patin (1601-1672) was a member of the Faculté de Médecine de Paris, and for a time the dean.

His letters of which a number of collections and editions were published after his death, were written during the period 1630-1672. As one would expect they are concerned largely with medical matters in Paris and France, but as he was not writing for publication he did not hesitate to attack men like Cardinals Richelieu and Mazarin, and organizations like the Jesuits or the Apothecaries.

His comments on physicians are at times rather cynical. Writing March 14, 1657 he says "The great are unfortunate in their physicians. The chief number of the court physicians are ignorant or charlatans, and often both the one and other." And on another occasion "I will say, to the shame of my art if doctors were only paid for the good that they actually do, they would not gain so much, but we profit from the foolishness of women, from the weakness of sick men, and from the credulity of everybody."

The book, mainly a reprint of articles that have appeared in the *Annals of Medical History*, is well printed, well made, and contains a number of illustrations, which add to its interest and value.

We can heartily indorse a statement of the author in the introduction, "that the letters give us an invaluable

picture of the life of the times, not only from the medical point of view, but in all its aspects." The letters are largely the source of the book.

IRA TRACY

**IMMUNITY IN NATURAL INFECTIOUS DISEASE** By F. D'HERELLE. Authorized English Edition by George H. Smith, Ph.D. Octavo of 399 pages Baltimore, Williams & Wilkins Company, 1924. Cloth, \$5.00

The reviewer ventures to predict that d'Herelle's work will ultimately be regarded as one of the important contributions to immunology. The present volume is one of absorbing interest, requiring careful study and proving many stimulating ideas.

This second volume from the pen of d'Herelle consists of a resume of his first work 'The Bacteriophage' with considerable new matter in which he attempts a correlation of bacteriophagy with the other phenomena of immunology. In fact, he advances a new concept of the mechanism of immunity which supplements without displacing prior conceptions. Whether or not one agrees with d'Herelle, his ideas are stimulating and the inevitable discussion of them will be valuable.

Parts 1 and 2 consist of a full discussion of the reactions of living matter and of the role of the colloids therein, and presents the author's 'micellar concept of life'. Part 3 deals with the reactions against bacteria, bacteriophagy in vitro and in vivo and the bacteriophage as a prophylactic and therapeutic agent. Part 4 presents a most interesting discussion of the ultraviruses in disease and immunity and classifies the bacteriophage with these ultra forms of life.

The reviewer is impressed with several similarities in the work and minds of Pasteur and d'Herelle. Both sailed uncharted seas, both were obliged to invent a new technique, both were seekers of facts and believers in experiments. d'Herelle's work reveals a remarkable mind and the same vivid imagination possessed by Pasteur. There is even a similarity in their literary styles.

This is the most stimulating book the reviewer has read in a long time.

E. B. SMITH

**GENERAL SYSTEMATIC BACTERIOLOGY** History, Nomenclature, Groups of Bacteria. By R. E. BUCHANAN, Ph.D. Baltimore, Williams & Wilkins Company, 1925. Octavo of 597 pages. Cloth, \$6.00 (Monographs of Systematic Bacteriology.)

This is the first of a series of monographs published under the editorial direction of the Society of American Bacteriologists. Its purpose is to present the phylogeny and relationship of various groups of bacteria and a nomenclature upon which all can agree. The author gives all the important classifications from 1773 to 1922, various codes of nomenclature and finally an alphabetical list of bacteria with proper names and descriptions. This work by Buchanan and a previous one by Bergey are useful in bringing order to a branch of science where everyone has proposed his own classification.

E. B. SMITH.

**A TREATISE OF INFLUENZA**, with special reference to the Pandemic of 1918. By RAJENDRA KUMAR SEN, Medical Officer, Hurmatty Tea Co., Ltd., Assam. John Bale, Sons & Danielsson, Ltd., Oxford House London W. I. 1923

This treatise on influenza is well worth reading. The author a native of India, has made a careful study of the disease especially as it appeared in India in 1918, and in addition has read extensively on the subject. He gives a history of the various outbreaks and then logically presents the results of his personal experience.

comment on the relation of cross-word puzzles to mental health, and quotes a pamphlet issued by the Chicago Department of Health in which the puzzles are called the "Mental Daily Dozen"

The quotation reads

"In the pamphlet, 'Chicago's Health,' issued by the Chicago Health Department, crossword puzzles are termed the 'mental daily dozen' The pamphlet explains 'Health of mind is of as much consequence to happiness as is health of body A rational cycle of work, study, relaxation and amusement is essential to the health of mind To solve a crossword puzzle requires mental alertness, concentration and strict application to order and rules Moreover, it's great fun Activity is increased under the influence of pleasant feelings, giving a stronger heart beat, stirring the glands to better performance and invigorating the organs of the body' All of which is something for the cross-word skeptics to put in their pipes and smoke"

The health effects of another popular fad are discussed in the March 9th issue of the New York *Sun* by Dr Harris of the Brooklyn State Hospital, who said

"Radio may be one of the causes for the overstrained condition of persons today Emotional intensity, which is created by a number of elements which characterize our civilization, in some minds may be brought to too great a pitch They may then be snapped by static"

On the other hand, Dr Blaisdell, Assistant Superintendent of the Kings Park State Hospital, is quoted as saying

"We have installed radio in some of our wards with very great success People who have enough mind and enough attention to be interested in their surroundings find in radio a link which connects them with the world beyond the walls which must confine them

"Our people are chiefly interested in music They will tune in on orchestral selections much more often than they will on speeches Music is soothing and beneficial for the disordered mind

"The wards in which the receiving instruments have been installed have patients who have received occupational therapy and habit training so that no scientific statement can be made as to the exact effect of radio I am of the opinion that it is generally beneficial and that only in extreme cases does the static really shock the listener"

It is the opinion of the editor that the *Sun* reporter was short on news when he quoted the two doctors

The *Utica Press*, March 20th, has a half column article on the three principal measurements of advancement or backwardness of a community, and enumerates them as follows

- 1 Hours of labor
- 2 Requirements as to school attendance.
- 3 Death rate

The article discusses each as follows

"In this country half a century ago a day's work comprised at least twelve hours, and in some occupations more In those days it was impossible apparently to get the world's work done unless everybody worked a dozen hours each day

"Half a century ago, also, few could send their children to school after they were eight or ten years of age They might have the desire to do better by their children, but they could not afford it Now a child must go to school in this state until he is 16, which goes to show that the parents are more prosperous than formerly and have perhaps a higher appreciation of the value of education

"As to the death rate, it is much lower than formerly, and individuals live longer Dr William H Guilfooy, registrar of records in New York City Health Department, who began this week his 41st year of service, has seen the death rate in New York drop from 25 per 1,000 to 11.6 per 1,000 in his forty years in the department"

These yardsticks are as reliable as any of a dozen others that might be used

The Brooklyn *Eagle*, March 21st, describes a hearing on water pollution held in Riverhead on March 20th, by Dr Matthias Nicoll, Jr, State Commissioner of Health, during which the authorities of the villages that sewer into the coastal water agreed to install modern disposal plants Some of the critics of the Department of Health brought up the point that most of the pollution off shore came from the fleet of war vessels which frequent Gardiner's Bay The government could keep the fleet away from Gardiner's Island, and then the shopkeepers of Greenport would have a grievance

The City of New Rochelle has attempted to prevent water pollution by houseboats, according to the March 16th issue of the New Rochelle *Star*, which says

"As to the yachts and houseboats, of which the various civic bodies have complained because of the garbage, refuse and offal cast in their vicinity upon the waters of the bay, the Board of Health adopted rules providing that the boats must henceforth be provided with sanitary facilities, probably by the use of septic tanks or similar devices, to prevent further possible pollution In this connection, it may be noted that only last week the owner of a houseboat mentioned in the office of the building department that he is installing a septic tank and that most of his colleagues on the bay are doing likewise"

# BOOK REVIEWS

**ESSENTIALS OF PRESCRIPTION WRITING** By CARY EGGLESTON, M.D. Third Edition, revised 146 pages Phila and London, W B Saunders Co, 1924 Cloth, \$1.50

In these days of intensive medicine when students and practitioners alike are so keenly interested in the rapid changes that are taking place in our knowledge of diseases, their causes, and treatment, the art of correct prescription writing seems to have been entirely neglected. The recent graduate, though properly instructed, seldom gives much time to this subject and the busy doctor likewise considers other things more important with the result that both are in a dilemma when prescribing and are at a loss to know how and in what way to prescribe so that their recipe is pharmaceutically, chemically and therapeutically accurate. In addition, little attention is given to grammatical construction. There are many books on this subject that are valuable but most are too voluminous to be practical. This present volume of Eggleston's, in its third edition, is concise and covers the essentials exceedingly well. The chapters on Latin grammar, grammatical construction of prescriptions, practical writing of prescriptions, vehicles, and incompatibility, are well worth reading. To those who wish to improve themselves in this art this little book will answer admirably.

FREDERICK SCHROEDER.

**THE ROMANCE OF A LIVING TEMPLE, A STUDY OF THE HUMAN BODY** By FREDERICK M. ROSSITER, B.S., M.D., L.C.R.P., M.R.C.S., London, Professor Medicine, College of Medical Evangelists, Los Angeles, Cal George Sully & Co, New York, 1924

This is a most elementary treatise on human physiology. By the use of very simple language and well selected comparisons the author has succeeded in presenting his subject in a way that will insure the sustained interest of the young readers for whom the book has been written.

FRANK E. MALLON

**GUY PATIN, AND THE MEDICAL PROFESSION IN PARIS IN THE XVIIth CENTURY** By FRANCIS R. PACKARD, M.D. Author of *Life and Times of Ambroise Pare*. Seventeen illustrations, nine full page plates. Paul Hoeber, Inc., New York, 1924 Price, \$4.00

Guy Patin (1601-1672) was a member of the Faculté de Médecine de Paris, and for a time the dean.

His letters of which a number of collections and editions were published after his death, were written during the period 1630-1672. As one would expect they are concerned largely with medical matters in Paris and France, but as he was not writing for publication he did not hesitate to attack men like Cardinals Richelieu and Mazarin, and organizations like the Jesuits or the Apothecaries.

His comments on physicians are at times rather cynical. Writing March 14, 1657, he says "The great are unfortunate in their physicians. The chief number of the court physicians are ignorant or charlatans, and often both the one and other." And on another occasion "I will say, to the shame of my art if doctors were only paid for the good that they actually do, they would not gain so much, but we profit from the foolishness of women, from the weakness of sick men, and from the credulity of everybody."

The book, mainly a reprint of articles that have appeared in the *Annals of Medical History*, is well printed, well made, and contains a number of illustrations, which add to its interest and value.

We can heartily indorse a statement of the author in the introduction, "that the letters give us an invaluable

picture of the life of the times, not only from the medical point of view, but in all its aspects." The letters are largely the source of the book.

IRA TRACY

**IMMUNITY IN NATURAL INFECTIOUS DISEASE**. By F. d'HERELLE. Authorized English Edition by George H. Smith, Ph.D. Octavo of 399 pages Baltimore, Williams & Wilkins Company, 1924 Cloth, \$5.00

The reviewer ventures to predict that d'Herelle's work will ultimately be regarded as one of the important contributions to immunology. The present volume is one of absorbing interest, requiring careful study and provoking many stimulating ideas.

This second volume from the pen of d'Herelle consists of a resume of his first work "The Bacteriophage" with considerable new matter in which he attempts a correlation of bacteriophagy with the other phenomena of immunology. In fact, he advances a new concept of the mechanism of immunity which supplements without displacing prior conceptions. Whether or not one agrees with d'Herelle, his ideas are stimulating and the inevitable discussion of them will be valuable.

Parts 1 and 2 consist of a full discussion of the reactions of living matter and of the role of the colloids therein, and presents the author's "micellar concept of life." Part 3 deals with the reactions against bacteria, bacteriophagy in vitro and in vivo and the bacteriophage as a prophylactic and therapeutic agent. Part 4 presents a most interesting discussion of the ultraviruses in disease and immunity and classifies the bacteriophage with these ultra forms of life.

The reviewer is impressed with several similarities in the work and minds of Pasteur and d'Herelle. Both sailed uncharted seas, both were obliged to invent a new technique, both were seekers of facts and believers in experiments. d'Herelle's work reveals a remarkable mind and the same vivid imagination possessed by Pasteur. There is even a similarity in their literary styles.

This is the most stimulating book the reviewer has read in a long time.

E. B. SMITH

**GENERAL SYSTEMATIC BACTERIOLOGY** History, Nomenclature, Groups of Bacteria. By R. E. BUCHANAN, Ph.D. Baltimore, Williams & Wilkins Company, 1925 Octavo of 597 pages Cloth, \$6.00 (Monographs of Systematic Bacteriology)

This is the first of a series of monographs published under the editorial direction of the Society of American Bacteriologists. Its purpose is to present the phylogeny and relationship of various groups of bacteria and a nomenclature upon which all can agree. The author gives all the important classifications from 1773 to 1922, various codes of nomenclature and finally an alphabetical list of bacteria with proper names and descriptions. This work by Buchanan and a previous one by Bergey are useful in bringing order to a branch of science where everyone has proposed his own classification.

E. B. SMITH

**A TREATISE ON INFLUENZA**, with special reference to the Pandemic of 1918. By RAJENDRA KUMAR SEN, Medical Officer, Hurmatty Tea Co., Ltd., Assam. John Bale, Sons & Danielsson, Ltd., Oxford House London W. I. 1923

This treatise on influenza is well worth reading. The author a native of India, has made a careful study of the disease especially as it appeared in India in 1918, and in addition has read extensively on the subject. He gives a history of the various outbreaks and then logically presents the results of his personal experience.

and his wide reading. The book is accurate, concise, inclusive and thorough. The chapter on symptoms presents the clinical features of the disease more completely and fully than many other papers. Treatment has been well presented. No one can study this treatise without being benefited by it. HENRY M. MOSES

A WOMAN'S QUEST, THE LIFE OF MARIE E. ZAKRZEWSKA, M.D., edited by AGNES C. VIETOR, M.D., F.A.S.C. D. Appleton and Co., New York, 1924 \$3 00

This volume contains the life history of Marie Zakrzeska, one of the first women to receive a Medical degree in America.

She was born in Berlin of Polish parents. At the age of ten an eye affection made hospital care necessary. Her physician led her blindfolded on his visits through the wards and the patients called her "The little blind doctor." When her eyes recovered she asked the doctor to give her books on history to read. He gave her the History of Surgery and of Midwifery—two big volumes. Although but eleven years of age she read them through and determined then that she would be a doctor, although she had never heard of a woman becoming one. With this inkling of how this woman was led to enter upon the study of medicine we launch into a fascinating account of the life history of this pioneer woman physician. The story of her life is an example of the difficulties encountered and the prejudice met and overcome in large measure by all the women who first entered the Profession of Medicine. It is a most thrilling story of an eventful life with which is interwoven the evolution of the American Woman Physician written by one of her hospital internes, whom she chose before her death to write it and to whom she left her letters and manuscript for the purpose.

ELIZA M. MOSHER

EYE HAZARDS IN INDUSTRIAL OCCUPATIONS, LOUIS RESNICK and LEWIS H. CARRIS, published by The National Committee for the Prevention of Blindness, Inc., 130 East 22nd St., New York City, 1924. Price \$1.50 and \$2 50

This volume of 211 pages will be read with interest and profit by Ophthalmologists, as well as employers of labor, everywhere. The need for uniformity of statistics regarding industrial eye injuries is stressed and emphasis is placed upon making the wearing of goggles compulsory in plants where there is an eye hazard. As was to have been expected, the investigation reported upon, shows that the metal industries show a greater incidence of eye injuries than do any of the others. The necessity of proper guards for machinery and of proper illumination of industrial plants in the prevention of accidents is pointed out.

A chapter on the correction of defective vision bears testimony to the fact that, in plants where employees are regularly submitted to examination regarding their vision and defects corrected, the occurrence of industrial injuries is diminished.

Education, of the State as to its moral and economic obligations, of the employer as to the desirability of supplying adequate protection for the eyes of his employees, and education of the employee as to the necessity of using that protection when it is provided, these, it is pointed out offer the greatest possibilities for the elimination of unnecessary eye hazards in industry.

Occupational diseases affecting the eyes are considered at length. JOSEPH E. GOLDING.

ANATOMY OF THE HUMAN BODY By HENRY GRAY, F.R.S. Twenty-first Edition, thoroughly revised and re-edited by WARREN H. LEWIS, B.S., M.D. Octavo, 1417 pages, 1283 illustrations. Phila. and New York, Lea & Febiger, 1924. Cloth, \$10 00

The first edition of Gray's Anatomy appeared in 1858, no doubt in the first review the concise language and clearness of description were deemed worthy of comment. And this is just as true of the 21st edition which is now presented after an interval of six years and has again been revised and re-edited by Professor Lewis. There is some new material and many new illustrations including striking reproductions of photographs. A change in the order of presentation of the subject matter in each section is noted, the embryology now being given in advance of the microscopical anatomy. The use of the B.N.A. nomenclature in English together with the English synonym has been retained practically unchanged. The references to the literature at the end of each section are more numerous.

Considerable material has been added to the sections on General Embryology and Angiology and the reproductions of reconstructions of the developing aortic and pulmonary arches are noteworthy. The description of the architecture of the heart muscle has been enlarged and the sino-atrial node is now described in connection with the muscular structure of the sinus venosus and atrium and it is no longer described as connected up by Bundle of His fibres with the atrio-ventricular node, thus conforming to Tawara's original contribution.

The section on Splanchnology which includes the Ductless Glands and the Chromophil and Cortical Systems, has been brought up to date. In the anatomy of the Nervous System there are new figures but no great amount of alteration of the subject matter of the text is noted. The triangles of the neck are now included in the section on Surface Anatomy and Surface Markings and less importance is attached to them than in former editions, new material based upon cross sections of the extremities has been added to this section.

The influence of the language of Henry Gray upon the English speaking medical mind can never be estimated. What better introduction to the new world of medical science can there be for the first year student? We can continue to recommend Gray's Anatomy to them with as little hesitancy as in the past.

JAMES L. COBB.

THE ERRORS OF ACCOMMODATION AND REFRACTION OF THE EYE AND THEIR TREATMENT, A Handbook for Students By ERNEST CLARKE, M.D., F.R.C.S., Consulting Surgeon Central London Ophthalmic Hospital. Fifth Edition. William Wood and Co., New York, 1924. Price \$3 50

The matter and method of presentation of this admirable little book lives up to its title very well.

The explanations and descriptions are clear and very much to the point. The work is accurate and trustworthy in all respects.

The diagrams and plates generally are good, and particularly interesting is the one the author has reproduced describing the optics of retinoscopy.

It is gratifying to note that such a work has been so successfully used in teaching undergraduates in general medicine in the English schools. This is the more pleasing because it seems to the reviewer that Ophthalmology, and particularly refraction, is given more attention by the general practitioner than in this country where such a work could scarcely be used on account of the limited time assigned for the entire subject of Ophthalmology. It is hoped that our English brothers do not sacrifice the medical aspects for the sake of the optical studies in so important a subject to the man who needs a good general understanding of the eye and its diseases. ## THE DIAGNOSIS OF ACUTE SURGICAL DISEASES OF THE ABDOMEN \*

By HENRY ROTH, M.D., F.A.C.S.,

NEW YORK, N Y

THE responsibility of the physician is never as great as when he is confronted with an acute intraabdominal condition in which the question must be answered whether or not the patient requires an immediate operation. An exact diagnosis may be very difficult and in some of the rarer conditions may even be impossible. It is sufficient, however, if we can determine that we are dealing with a serious intraabdominal emergency which demands immediate operation. Owing to the very grave condition in which many of the patients are found, the risk of an operation is very great, and therefore our responsibility is so much greater. We are liable to adverse criticism whether we try to be conservative and advise an operation too late, or whether we occasionally resort to an operation which subsequently proves to have been unnecessary. In spite of the fact that this subject has been dealt with on many occasions, the mortality rate of acute intraabdominal conditions is still very high. This to a great extent is due to the fact that many of the patients are operated upon too late, or after too long a period of time has been allowed to elapse between the onset of the symptoms and the time of operation. This, undoubtedly, is due to the difficulties met with in diagnosis, and while it would seem as if everything worth while has been said, there is still very much which can be learned from a further consideration of the subject. With this in mind I will endeavor to discuss some of the most important factors in the diagnosis of the acute non-traumatic intraabdominal conditions. The diseases which belong under this heading are many and varied. Many of them occur as acute emergencies in connection with pre-existing chronic diseases, such as gastric and duodenal ulcers, gallstone disease, and tumors of the gastrointestinal tract and the female generative organs. In another group of cases the acute condition is due to some obstruction in the intestinal canal. In a smaller group the cause of the emergency

is bleeding into the peritoneal cavity, and in a still smaller class the emergency is due to torsion of structures with consequent circulatory disturbances.

In all of these conditions severe abdominal pain is the first and foremost symptom. This is soon followed by tenderness, rigidity and vomiting. The appearance of this combination of symptoms and signs is indicative of a serious intraabdominal condition. In attempting to make an exact diagnosis nothing will be of greater value than a carefully taken clinical history and its logical interpretation. In many instances the history alone may point to the correct diagnosis, but in every case the history should be supplemented with a careful physical examination. To discuss the significance and importance of all the various symptoms and signs as related to the diagnosis of all the various intraabdominal conditions requires more time than we have at our disposal. I will, therefore, limit my remarks to those conditions which are most frequently met with in our every day practice.

Experience has shown that of all the acute intraabdominal conditions, acute appendicitis is the most common disease. Acute cholecystitis comes next in frequency. Then follow cases of acute perforations of chronic duodenal and gastric ulcers, the various forms of acute intestinal obstruction, ruptured extrauterine pregnancy, and acute infections and torsions of the female generative organs. The more uncommon diseases which we have to bear in mind are acute pancreatitis, mesenteric thrombosis, mesenteric adenitis, pneumococcus peritonitis, acute tuberculous peritonitis and acute sigmoid diverticulitis. Owing to the fact that pain, tenderness, rigidity and vomiting are present in most of the acute intraabdominal diseases, an exact diagnosis is often very difficult, but by a process of elimination can usually be made in most instances, providing the various conditions are ever borne in mind. In this process of elimination many factors have to be considered. In most of the conditions there is some outstanding feature in the history or

\* Read before the Bronx County Medical Society November 19, 1924.

some outstanding symptom or sign which points more definitely to some one particular disease. It is this outstanding feature which directs our attention to the most likely condition which may be confronting us. The age and sex of the patient and the relative frequency of the various conditions occurring at different ages and in the two sexes are of great importance. For instance, if the patient is an infant under one year of age, the most likely condition causing the above symptoms will be an acute intussusception. If the child is over two years of age the most likely conditions which we have to consider are acute appendicitis, pneumococcus peritonitis and acute pyelitis, the latter being more common in female children. In a young man or young woman acute appendicitis is more apt to be present than acute cholecystitis or acute Meckel's diverticulitis, the latter condition being extremely rare. Acute cholecystitis is more likely to be present if the patient is a married woman, especially if she has borne children and is stout, and if the first attack occurs soon after childbirth. Acute sigmoid diverticulitis usually occurs in individuals past middle age who are very stout, whereas attacks of Dietl's crises are more common in younger women who are very thin. In very young girls an acute pelvic infection is less likely to be present than torsions of an ovarian cyst pedicle. Some menstrual irregularity in a woman during the child-bearing period should strongly suggest the possibility of a ruptured extrauterine pregnancy.

The character of the pain often helps in making a differential diagnosis. If the pain is of a paroxysmal character, renal, biliary and intestinal colic have to be considered rather than an acute infection or perforation.

If the patient is a married woman and especially if she has just given birth to a child, the colic is more apt to be of a biliary nature than due to an acute intestinal obstruction or to an obstruction in the ureter, especially if the pain radiates to the back or right shoulder. If the pain radiates towards the groins or genitals and especially if it is associated with some urinary symptoms, a diagnosis of renal colic is more apt to be right than one of biliary colic or intestinal obstruction. If with the above symptoms there is a history of a preceding abdominal operation, or of a preceding pelvic inflammation, acute intestinal obstruction due to strangulation by bands, or angulation due to adhesions, is the most likely condition present. In women, a strangulated femoral hernia is very often the cause of the acute obstruction, even though it appears only as a very small lump in the groin, not unlike an enlarged lymph node. Such a small lump in the groin in a patient with symptoms suggestive of an acute intestinal obstruction should always be looked upon as a strangulated femoral hernia until it is proven to be otherwise. If the patient is past

middle age, and especially if there is a history of preceding mild attacks of colic, the intestinal obstruction is very often due to an annular constriction of the colon, caused by a malignant neoplasm. This condition, however, is not infrequently seen even among young individuals. The presence of a hernia should also suggest the possibility of an acute torsion of the omentum as the cause of the symptoms. Nor should we forget that the above symptoms with a very painful lump, in the groin of a boy, may be indicative of an acute torsion of the spermatic cord.

A history of indigestion and pain after eating may be helpful in promptly recognizing an acute perforation of a chronic duodenal ulcer because of its greater frequency. If the patient gives a history suggestive of cholelithiasis, acute hemorrhagic pancreatitis must always be thought of, especially if the illness began with the manifestations of shock, and there is marked distention in the epigastric region. If the patient has a valvular lesion of the heart, the possibility of a mesenteric thrombosis must not be forgotten. During epidemics of influenza it is of the utmost importance to bear in mind that this condition is at times associated with abdominal pain, tenderness and vomiting. The presence of echymotic spots on the skin should immediately suggest the possibility of Henoch's purpura. A history of hemophilia should prevent the mistaking of a retroperitoneal blood clot for an appendiceal abscess. In our attempt to make an exact diagnosis, the comparative frequency of the various conditions should always be considered. Acute intussusception is the most common variety of intestinal obstruction occurring in infants and very young children. Intestinal obstruction caused by bands and by new growths occur much more frequently than obstructions caused by a volvulus of the sigmoid. Torsion of the omentum and of the spermatic cord are very rare, whereas torsion of an ovarian cyst pedicle is not quite so rare. Acute pelvic infections are more common than ruptured extrauterine pregnancies. Acute appendicitis and pneumococcus peritonitis are the most common acute intraabdominal conditions found in children.

In my experience almost seventy-five per cent of the operations done for acute intraabdominal conditions were for acute appendicitis. It will, therefore, be advisable to devote most of our attention to the diagnosis of this, still the most important of all acute intraabdominal diseases. It occurs at all periods of life, but is rare in infants. The clinical picture of the disease has been so often presented and is so well known that it would seem like a waste of time to say anything further about it. Yet many cases of acute appendicitis still go unrecognized for some time after the onset of pain, and on the other

hand, the diagnosis of acute appendicitis is often made when some other condition exists. This, undoubtedly, is due to the fact that some of the cases do not strictly conform to the classical type, or because the symptoms and signs are inaccurately interpreted. Acute appendicitis usually begins abruptly with severe pain in the abdomen. If pain is not the first symptom to appear, one should hesitate about making a diagnosis of acute appendicitis. Vomiting occurs in most of the cases soon after the appearance of the pain and is usually repeated. There is a rise in the pulse rate which is soon followed by some rise in the temperature. The temperature may or may not be preceded by a chill. When a chill occurs it usually signifies gangrene. There is usually an increase in the number of white blood cells. While I fully realize its value and always insist upon a complete white cell count as a part of a complete physical examination, I do not rely upon it to the exclusion of other symptoms or signs. If it is confirmatory of the other clinical signs it is considered for what it is worth, but it is rarely the deciding factor in the diagnosis. This attitude is due to the fact that a low blood count does not necessarily indicate the absence of pus any more than that a high leucocyte count always points to a serious infection. It is a very dangerous practice to delay diagnosis and operation for blood counts.

Tenderness and rigidity of the abdominal wall being the most significant of the physical signs, it is of great importance that all possible care be taken in eliciting these signs. Palpation should be gentle, because rough pressing and squeezing will cause pain and produce voluntary rigidity in any case. It is important that superficial hyperesthesia be not mistaken for real tenderness. Palpation should begin at a point remote from the suspected area. In suspected acute appendicitis, I always begin with palpation over the left iliac fossa. I then proceed upward on the left side, then palpate the epigastric and right hypochondriac regions, and lastly palpate over the right iliac fossa. The fingers can often be pressed in deeper and deeper during expiration, thus enabling the examining fingers to feel an exudate, if one is present. Rigidity is always most pronounced over the primary lesion. If the appendix is in the right iliac fossa, rigidity is most marked in this area. When the appendix is in the pelvis, the rigidity is usually most pronounced near and to the right of the median line, or just above the pubis. When marked rigidity is also found over the left iliac fossa, the pelvic fluid exudate has very likely overflowed the pelvic brim and is spreading into the left iliac fossa. If tenderness and rigidity are most marked in the right flank, the appendix is most likely behind or to the outer side of the ascending colon. When, as a result

of perforation or gangrene, peritonitis becomes diffuse, tenderness and rigidity spread toward the left side and gradually extend over the entire abdomen. The latter condition is greatly favored by the very prevalent practice of giving purgatives with the onset of the abdominal pain. Indeed, many surgeons ascribe the high mortality of acute appendicitis as much to the giving of purgatives as to delay in operating, because purgation favors perforation and gangrene and because by increasing peristalsis it spreads the infection.

The diagnosis of acute appendicitis is more difficult in children, especially in those under five years of age, because of their inability to describe their symptoms and because of the difficulty of making a satisfactory examination and also because of the frequency with which children complain of abdominal pain in connection with other diseases. This is especially the case in acute inflammatory conditions of the pleura and lungs, in which the pain is referred from the chest along branches of the lower intercostal nerves. It is of the utmost importance that pneumonia and pleurisy be excluded so as to avoid an unnecessary operation, with its grave risks from the anæsthetic. On the other hand, it is even more important that so serious a condition as acute appendicitis be not overlooked. In cases of pleurisy or pneumonia the tenderness is superficial and the palpating hand will meet with less and less resistance as the examination proceeds. The abdominal wall relaxes because there is no real tenderness present. Because of the delay in the appearance of physical signs, the most reliable method for the exclusion of pneumonia in these cases is an X-ray examination of the chest, which can be done without much delay, and with absolute freedom from all risk. A child with acute appendicitis usually cries constantly and is not apt to fall asleep for any length of time, whereas a child with pneumonia is often asleep for long periods of time, has a flushed face, a high temperature, higher leucocytosis and looks extremely ill.

Palpation in children must often be done under great difficulties, because children often resist all attempts at examination. It frequently has to be done during the very brief periods of rest from crying. I always attempt to win the child's confidence before I begin abdominal palpation, and try not to restrain its movements in any way, leaving the hands free, preferably alongside the body. I then proceed with palpation. If the child makes no attempt with its hands to guard its abdomen or to push away my examining hand, I feel quite confident that the child has no intraperitoneal inflammation. The failure on the part of the child to protect its abdomen against the examining hand is to my mind one of the most valuable signs indicative of the absence of an

acute intraperitoneal inflammation I have learned to rely upon this sign in children more than upon any other single sign or symptom. It has been more helpful than any other sign in determining the absence of acute appendicitis in children. Palpation should always be supplemented with a rectal examination, because of the valuable information which it may furnish in the absence of other reliable physical signs. Of the many conditions which may simulate acute appendicitis in children, pneumococcus peritonitis is the most important.

The diagnosis of pneumococcus peritonitis presents many difficulties. The condition usually occurs in young children, and in girls more frequently than in boys. Often there is a history of diarrhoea preceding the appearance of abdominal pain. In addition to pain there are present all the usual symptoms and signs of peritonitis, such as tenderness, rigidity and vomiting. There is a marked rise in the temperature, it may reach as high as  $105^{\circ}$  F, with a corresponding rise in the pulse rate. Leucocytosis is much higher than in acute appendicitis. There is marked prostration and toxemia, such as is seen in pneumonia. The constitutional symptoms as a rule overshadow the abdominal signs. Most of the cases occur independent of any lung involvement. If the patient survives the acute stage of the disease and the peritoneal exudate becomes encapsulated, an indefinite doughy tumor mass may be felt in some part of the abdomen. The mistake which is most likely to be made is that a pneumococcus peritonitis is mistaken for acute appendicitis. In differentiating acute pneumococcus peritonitis from other acute intraabdominal conditions, exploratory aspiration of the abdominal cavity with a specially constructed needle and examination of a smear from the aspirated fluid may furnish valuable information regarding the particular organism which is causing the infection.

The conditions which are most apt to simulate acute appendicitis in children besides pneumonia and pleurisy and pneumococcus peritonitis, are mesenteric adenitis, Henoch's purpura and acute throat infections, acute pastro-enteritis with or without acute acidosis, influenza with abdominal symptoms, acute pyelitis, infections of the iliac and inguinal lymph glands, acute Meckel's diverticulitis, stone in the bladder, ovarian cyst or tubular infections in little girls, and torsion of the spermatic cord in boys. Acute infections of the gall bladder and acute perforations of chronic gastric and duodenal ulcers are extremely rare in children. As a matter of fact, in children past infancy, acute appendicitis is the commonest acute intraabdominal condition requiring surgical treatment. Acute appendicitis in adults may be simulated by almost every one of the conditions mentioned above, and by many others, such as acute pancreatitis, acute sigmoid diverticulitis, biliary

renal or ureteral colic, acute hematogenous septic infarctions of the kidney, Dietl's crises, acute intestinal obstruction, torsion of the omentum, lead colic, the abdominal crises of locomotor ataxia, and even typhoid fever and malaria have been known to simulate acute appendicitis.

After acute appendicitis, acute infection of the gall bladder comes next in importance. Biliary colic occurs very often. Acute perforation of the gall bladder is extremely rare. As stated above, acute cholecystitis is very rare in children. The history often reveals the fact that the patient had typhoid fever at some time in the past. A woman may state that her first colic occurred soon after childbirth or during pregnancy. There may be a history of chronic indigestion, eructations of gas, flatulence and biliousness. A very valuable part of the history is the statement that many of the attacks of so-called indigestion have come on during the night, waking the patient from her sleep.

As in acute appendicitis, so also in acute cholecystitis, pain is the outstanding symptom. The pain of biliary colic starts abruptly in the upper part of the abdomen, shoots through to the back and radiates to the chest, or right scapular region. It is usually very severe and agonizing, and may induce collapse. It may stop as abruptly as it started, but usually recurs in paroxysms. It may last from a few minutes to many hours, and be followed by pain of less severity, localized to the right hypochondriac region. So-called biliary colic may occur even in cholecystitis without calculi. Tenderness is not as constant a symptom as pain. It is most marked in acute infection, and its maximum point of intensity corresponds to a point slightly to the left and below the junction of the right ninth rib and its cartilage. It may be present all over the right hypochondriac and epigastric regions. With pain and tenderness there is usually rigidity of the upper part of the right rectus muscle, the extent and degree depending upon the degree of inflammation. It may be diffuse in the earliest stages of infection, and then become more localized, and be most marked in the region of the gall-bladder. It is most pronounced in the severe forms of acute cholecystitis, with diffuse peritonitis. With the onset of acute cholecystitis the temperature may reach  $101^{\circ}$  or  $102^{\circ}$  F, in suppurating and gangrenous cholecystitis it may be preceded by a chill and reach as high as  $103^{\circ}$  to  $105^{\circ}$  F, although it may be but slightly above normal even though the gall bladder be filled with pus. There is a corresponding rise in the pulse rate and hyperleucocytosis. Nausea or vomiting is present with biliary colic, which it often relieves. Vomiting may be present at the onset of acute cholecystitis, and is then usually the result of reflex irritation. A swelling or tumor may be present if the gall bladder is markedly distended, and it may even

attain a very large size and extend down into the right iliac fossa. It is usually pear shaped, continuous with the edge of the liver, and moves with respiration. In very thin patients it may be visible and movable from side to side. In some cases of acute cholecystitis a tumor cannot be felt either because the swelling extends inward and backward under the liver, or because tenderness and rigidity interfere with satisfactory palpation. There may be a tongue-like projection of the liver, known as Riedel's lobe. In acute cholecystitis, jaundice is only present if the infection spreads to the common or to the hepatic ducts. When a complicating cholangitis is present, jaundice is very pronounced. When the common duct is completely and acutely obstructed by a stone, jaundice is very pronounced and constant. The temperature usually shows an abrupt rise to a high degree,  $105^{\circ}$  to  $107^{\circ}$  F, preceded by a chill, associated with profuse sweating, and followed by a marked drop to normal or subnormal. These exacerbations recur at varying intervals, and may continue for several weeks. With the rise in the temperature there is a corresponding rise in the pulse rate and leucocytosis, and other evidence of a general systemic infection. The gall bladder in these cases is usually contracted, therefore a palpable tumor is not present. The stools are clay colored and the urine contains bile pigment.

Biliary colic and acute cholecystitis may be simulated by acute appendicitis and also by the various conditions which have been mentioned as being likely to simulate acute appendicitis. Acute cholecystitis is especially apt to be simulated by acute appendicitis if the appendix or some part of it is situated high up under the liver, but in acute appendicitis the initial pain as a rule does not radiate to the back or to the right shoulder, tenderness and rigidity are at a lower level, while in acute cholecystitis they are most pronounced over the upper part of the right rectus muscle, even if the gall bladder is very much below its usual level. Acute appendicitis is always associated with a rise in the temperature, while in acute biliary colic, which does not go on to cholecystitis, there is no systemic disturbance. In fact, acute appendicitis, as a rule, is associated with more marked constitutional disturbances than acute cholecystitis, unless the latter be of the gangrenous or perforating variety. In renal colic which occasionally simulates biliary colic, tenderness is usually most pronounced in the costovertebral space. There is also pain on fist percussion, the so-called Murphy sign. With Dietl's crises a movable kidney may be palpable, and there may be some urinary symptom. In considering the possibility of the pain being due to the gastric crises of tabes, it is well to bear in mind that even a tabetic patient may have gall stones or acute appendicitis.

Acute cholecystitis may be simulated by acute pancreatitis. Both conditions occur in the same type of patients. In fact, acute pancreatitis usually occurs in patients who have gall bladder disease. It is, therefore, more common in women than in men, and in stout people more so than in the thin. The attack begins with excruciating pain in the upper part of the abdomen, radiating to the back. With the onset of pain the general condition of the patient becomes very bad, the pulse rate is rapid and feeble, the extremities are cold and the skin is clammy and cyanosed. There is very marked rigidity in the upper part of the abdomen, which develops promptly with the onset of pain. There is usually great distention, which is especially marked in the epigastric region. There is vomiting from the very beginning and hiccough is apt to occur as in all cases of peritonitis. The diagnosis is but rarely made before operation.

Acute perforation of a chronic duodenal or gastric ulcer may occur at any age and in either sex, although it is more common in men in the prime of life. In many of the cases there may be no history of any pre-existing symptoms. Sudden perforation into the free peritoneal cavity is one of the most serious surgical emergencies and, therefore, in the presence of the symptoms and signs of an acute perforative peritonitis, the possibility of an acute perforation of a chronic ulcer of the duodenum or stomach must always be considered. This is very important to bear in mind so as to avoid overlooking a condition which is so easily remedied by an early and appropriate operation. The diagnosis of this condition is made with much greater ease during the earliest hours after the perforation, and may be impossible if the patient is seen at a later stage, when symptoms of a diffuse or generalized peritonitis have developed. A diagnosis may be very difficult or impossible if the symptoms and signs are masked by the injudicious administration of morphine, which has the effect not only of distorting the clinical picture, but of causing seeming improvement in the general condition of the patient.

The outstanding symptoms and signs of perforation are pain, tenderness and rigidity of the abdominal wall. The rigidity is general and complete, but is usually most marked in the upper part of the abdomen in the region overlying the ulcer. It is board-like in character and in the beginning produces retraction of the abdominal wall. If the patient is seen a number of hours after the beginning of the illness, pain, tenderness and rigidity will be very marked in the region of the appendix, on account of the gravitation of septic material into the right iliac fossa. At this time there may be a diminution in liver dullness and on percussion the signs of fluid may be demonstrable in the right flank. Acute per-

foration of a duodenal or gastric ulcer may be simulated by any one of the acute intraabdominal conditions, and even by a beginning pneumonia or pleurisy of the diaphragmatic type. It has been mistaken most frequently for acute appendicitis. In fact, some of the earliest reported cases were only discovered during operations for supposed acute appendicitis. If seen early, acute perforation of an ulcer may be and is now very frequently diagnosed before operation. The initial pain of acute perforation is very much more severe than that of acute appendicitis. It begins more abruptly and the rigidity and tenderness are more pronounced in the upper abdomen, more so than in acute appendicitis. Furthermore, the rigidity in cases of acute appendicitis is not quite as marked or board-like in character, unless the appendiceal infection is exceptionally virulent. As a rule the symptoms and signs of diffuse peritonitis develop much more rapidly in acutely perforated ulcers than in acute appendicitis, because septic material escapes more quickly and in larger quantities through the perforation. Acute inflammation of a Meckel's diverticulum does not, as a rule, begin with such agonizing pain, nor is the rigidity so marked in the epigastric region. Furthermore, the condition is very rare as compared with acute perforation of duodenal or gastric ulcers.

Acute intussusception forms about one-third of all varieties of acute intestinal obstruction. Most of the patients are under twelve months of age. In infants it is attended by a characteristic chain of symptoms which should lead to an early diagnosis and prompt and appropriate treatment. The disease usually begins suddenly in previously perfectly healthy infants. The first and foremost symptom is pain, which is usually colicky in nature. The child screams and draws up its legs with each paroxysm. With the onset of pain there is a marked change in the general appearance of the little patient, characterized by the various manifestations of shock, such as an anxious expression of the face, pale skin, rapid and feeble pulse, cold perspiration, and shallow breathing. In fact, the patient presents the appearance of one who is very ill. This is of very great diagnostic value, because acute intussusception usually occurs in children who only a few hours before presented the picture of perfect health. Soon after the appearance of pain there is vomiting, which recurs, first at long and later at shorter intervals, and may become projectile in character. The vomitus is usually bile stained fluid. Several hours after the onset of pain there may be an escape of bloody mucus from the rectum. The child may have had a movement from the bowels which may have been blood stained, or may have absolute constipation, dating from the time of the first symptom. At times there

may be no escape of blood or bloody mucus from the rectum until a rectal examination is made, when on withdrawing the finger a bloody mucus discharge is seen. This group of symptoms is pathognomonic of the disease. In the beginning there is no abdominal distention, the abdominal walls are more likely to be relaxed than rigid, and during the paroxysms of pain there may be observed a tumor or fullness. On palpation a tumor may be felt and most frequently in the right side of the abdomen. Many times the tumor is palpable in the left side of the abdominal cavity. At times it cannot be felt at all, because it is hidden under the lower ribs. When not otherwise palpable, a tumor or fullness may be felt during the paroxysms of pain. In other cases it may be detected on bimanual examination with one finger in the rectum. In a few cases the examining finger in the rectum may detect the apex of the intussusception. In the beginning, there is no rise in the temperature, on the contrary, there may be a subnormal temperature. After a number of hours the vomiting and bloody discharge from the rectum becomes more frequent and the child appears to suffer from rectal tenesmus. The latter symptom is most marked in those cases in which the apex of the intussusception is in the rectum. If the disease is allowed to go on without recognizing its true nature, the symptoms of bowel gangrene and peritoneal sepsis develop. The temperature and pulse rate rise, the child becomes listless, shows general muscular relaxation, with sunken eyes, the extremities become cold and cyanosed, and the child appears absolutely indifferent to its surroundings. The abdomen becomes greatly distended with marked rigidity of the abdominal walls. Vomiting is almost continuous and the vomited material has a stercoraceous odor.

All other varieties of acute intestinal obstruction begin suddenly with pain which recurs in sharp paroxysms and which is due to the very violent peristalsis and distention of the bowel. In cases of acute obstruction secondary to carcinoma of the colon, there is usually a history of colicky pain for some time before the obstruction, but is usually felt in the umbilical region. In the cases of obstruction due to a neoplasm in the sigmoid colon, the maximum pain is in the lower part of the abdomen. The exact site of the obstruction can but rarely be determined before operation. In all suspected cases of acute intestinal obstruction the various hernial sites should be examined so as to determine whether or not the obstruction is due to a strangulated hernia. The most reliable sign in cases of intestinal obstruction is visible peristalsis. This is especially marked in those cases where the acute obstruction supervenes upon a slowly developing obstruction caused by a malignant growth in the colon. This

sign may sometimes be elicited by palpating the abdomen firmly and stimulating the bowel to peristalsis. When looking for it the patient should be observed in a good light. The loops of bowel are visible during the paroxysms of violent pain. They are especially marked if the small bowel had time to become hypertrophied and distended, or if the abdominal wall is very thin. The latter condition permits the wave-like movement of the coils of intestine to be seen without any difficulty. Inasmuch as this sign of intestinal obstruction only appears during a paroxysm of pain and disappears very quickly, it is necessary at times to watch the patient for some length of time before it appears. Owing to the great distention which is present in most of these cases, it may be impossible to feel a neoplasm of the colon, even if one is present. In cases of volvulus of the sigmoid the bowel may be palpable as a large tumor which is tympanic on percussion.

Soon after the appearance of pain there is vomiting, which at first is due to reflex irritation, and later on to obstruction to the normal flow of the intestinal contents. Continued vomiting of intestinal contents after repeated gastric lavage is almost conclusive evidence of intestinal obstruction.

The outstanding features of ruptured tubal pregnancy are sudden excruciating pain in the abdomen, followed by the symptoms and signs of an acute hemorrhage and preceded by a history of some irregularity in menstruation. The clinical picture of this condition is as a rule so typical that the diagnosis is readily made, especially if the history is taken carefully. There is usually a history of the patient having missed a menstrual period. Some time after this missed period, usually about a week or two after, the patient begins to have some vaginal bleeding, but not quite as much as with normal menstruation or with an abortion. In fact, the patient states that she spots rather than bleeds. Soon after the appearance of the bleeding the patient is suddenly seized with a most excruciating pain in the abdomen. Some of the patients give a history that while trying to move the bowels, they suddenly felt as if something had burst in the abdomen and that they fainted and fell to the floor. When picked up many of the patients are in a state of shock, with blanched lips and conjunctiva, and a very rapid, feeble pulse rate, marked restlessness and at times even air hunger. On vaginal examination there can usually be found tenderness and evidence of an exudate

in Douglas' pouch. Occasionally the enlarged tube can be felt. The early changes of pregnancy may be present in the breasts.

The differential diagnosis between ruptured ectopic pregnancy and acute infections of the adnexa and acute appendicitis often presents very great difficulties, especially if the appendix happens to lie within the pelvis. Vaginal examination is indispensable in these cases and usually reveals signs which aid in the diagnosis. With infections of the tubes there is marked tenderness in the pelvis. Severe pain is induced by pushing the cervix upward or trying to move it from side to side. The uterus is fixed and there may be evidence of an exudate in Douglas' pouch or there may be a tender tumor mass on one or both sides of the uterus.

In cases of torsion of some intraabdominal or pelvic tumor there is rarely such marked rigidity nor do the symptoms of peritonitis develop with such rapidity as in acute ulcers, perforations, or in acute appendicitis. Furthermore, a rapidly growing tumor can usually be felt in the lower part of the abdomen. The physical signs are most pronounced over the tumor. There may be a history pointing to the previous existence of a tumor.

In mesenteric thrombosis there may or may not be bleeding from the rectum or blood in the vomited material. Abdominal distention is pronounced very early in the disease. Acute mesenteric adenitis is comparatively rare and will but rarely be diagnosed correctly. Most of the cases are diagnosed as acute appendicitis before operation.

In tuberculous peritonitis there is likely to be marked abdominal distention owing to the ascites which is present in many of these cases. Indefinite irregular tumor masses can be felt in the abdomen, in some of these cases. The rolled up, thickened omentum is often felt as a distinct mass lying transversely in the upper abdomen.

In sigmoid diverticulitis the physical signs are the same as in acute appendicitis, excepting that they are low down on the left side of the abdomen.

In conclusion, it should be emphasized that a correct diagnosis in acute intraabdominal conditions can result only from a carefully taken history, accurate observations and a proper interpretation of the symptoms and signs. In the diagnosis of obscure cases a good clinical history is often more valuable than any other factor, because it sheds more light upon the cases than even a painstaking physical examination.

## FRACTURES OF THE HUMERUS\*

By HAROLD E. SANTEE, M.D.,

NEW YORK, N. Y.

When honored by an invitation from this association to read a paper on "Fractures of the Humerus," I was expressly told to "make it practical." This same request seems to be general at the present time and certainly any method for the treatment of fractures must be practical to obtain any kind of consideration. We all know of the present efforts of the American College of Surgeons to gradually work out a plan for the treatment of fractures which shall be based upon a thorough consideration of the pathology involved and shall draw from this consideration a plan of treatment which is more or less standardized for the various types of major fractures. The mere fact that men of ripe experience throughout the country are devoting time and thought to a review of such a subject as "Fractures" is indicative of a healthy attitude on the part of the profession and should be a source of hope to all of us. However, let us also hope that any method of standardization which may result will be elastic enough to permit of that degree of individualism in treatment which is the source of progress and advancement in any branch of our profession.

Since 1916 we have admitted to the Second (Cornell) Surgical Division at Bellevue Hospital, 170 fractures of the humerus. Of this number 83 were fractures about the upper end of the humerus, 66 of the shaft, 21 of the lower end. Only 10 have been under 20 years of age (our service admitting none under 12), so that any remarks I make are applicable to these fractures as they occur in adults. Of this total number of fractures, 17 were compound, two being crushing comminuted fractures which completely blocked the circulation and necessitated immediate amputation. The 15 remaining cases bring up that interesting question as to whether every compound fracture should be operated on. These cases were treated as follows:

Debrided, 10—Clean, 6, Infected, 4

Not Debrided, 5—Clean, 3, Infected 2

We realize that the above number is altogether too small to be the basis of any valuable deduction, nevertheless, when we add to this number our compound fractures of other bones in the body, we feel that we have a sufficient number on which to base reasonable judgment of this question. Our attitude at the present time is to consider the compounding of any major fracture an indication for immediate operation, such operative procedure

to include a careful toilet of the region surrounding the site of compounding, adequate exposure of the lacerated tract, a careful debridement of lacerated devitalized tissue and removal of blood clot, good hemostasis, continuous sponging or irrigation with Dakin's solution, removal of unattached bony fragments, reduction of the fracture to good anatomical alignment, and to conclude with either a primary closure, a delayed primary closure or a secondary closure after Carrel-Dakin treatment, depending upon the judgment of the surgeon in charge. We believe our results support this method. While recognizing exceptions to its advisability in every case, nevertheless we feel strongly that such a procedure cleanses a wound of infected material, removes the best culture medium for such infection and establishes at once a condition in the wound which makes for prompt, adequate drainage and treatment should such infection supervene. This last feature alone seems to make it well worth while, for it takes into consideration that human element in all of us which makes us hesitate day after day to interfere in that mildly infected type of compound fracture which ultimately runs on to a terminal osteomyelitis of the bony fragments, slow sequestration, and possibly non union or chronic osteomyelitis.

In reviewing these fractures of the humerus for presentation before this association I would divide them for discussion into three types—fractures about the upper end (83), the shaft (66), and the lower end (21).

In our cases, fracture about the upper end of the humerus is an injury of middle life and beyond. Our cases average well above 50 years of age. The causative violence is usually direct. The resulting fracture may involve the anatomical neck, the greater or lesser tuberosity or the surgical neck, with or without accompanying dislocation. We have found fractures of the anatomical neck (4) and lesser tuberosity (2) rare. Fracture of the greater tuberosity alone has occurred seven times, twice accompanied by anterior dislocation. In no case was the displacement marked after reduction of the dislocation. The subsequent disability, however, in abduction and rotation has been marked and prolonged, and we now accord this fracture the same care from the outset that we give to the apparently more major fractures about the shoulder.

Fractures of the surgical neck (70) are the most frequent of the fractures of the humerus

\* Read before the New York and New England Association of Railway Surgeons at its Annual Meeting, New York, October 25, 1924.

as we meet them A majority of these present a gross displacement with either a single line of fracture or combined with added fracture through the greater tuberosity The displacement resulting is as a rule typical and combines abduction and external rotation of the small upper fragment with inward and upward displacement of the shaft This displacement should be borne in mind in treatment as its presence modifies our treatment to some extent Associated with these bone displacements is an injury to the soft parts which from the standpoint of treatment must be accorded equal importance with the bone injury

Treatment—The disability anticipated in these fractures about the shoulder manifests itself in three ways, limitation in abduction and rotation and loss of strength I am informed by the Compensation Commission in New York that their average disability in these cases runs from one to two years Treatment to justify itself completely must recognize not only the injury to the bone and soft parts, but the potential disability The most advantageous position for these cases to convalesce in is that of abduction and external rotation While this position may be attained by a plaster spica or aeroplane splint, we feel that it is best accomplished by suspension, traction abduction and external rotation with the aid of the Balkan frame The attainment of wide abduction may necessarily have to be gradual (7 to 10 days) as wide abduction early in some of these cases results in angulation at the site of fracture, but once attained along with external rotation, it places the bones and soft parts in such position that two of the factors in disability are largely overcome at the outset Such position is maintained for from 25 to 30 days Hospitalization is a requisite, but this disadvantage is, I feel, more than overcome by the shortened period of disability Speed in recovery depends largely on the active co-operation of the patient himself in maintaining by graduated active exercise the above position Only by continued use will strength return Physiotherapy and massage are aids in convalescence, but the shortest disability is the reward of the actively co-operative patient

Fractures of the shaft of the humerus offer somewhat different problems from those near the end In our series of 66 the age incidence is lower, the etiological factor as far as can be ascertained showing slightly more by direct violence than indirect Angulation and overriding are the rule whether the line of fracture is oblique, spiral or transverse, but no typical position of the fragments seems characteristic The associated soft tissue injury involves adjacent joints to a lesser degree hence some pathological considerations present at the end of the bone are absent in the shaft Other

factors, however, have to be considered—namely, musculo-spiral paralysis and delayed or non-union In 66 cases, musculo-spiral paralysis has been encountered five times Observation as to its presence or absence on admission of the case should always be made It has been our custom to wait until union has occurred, then to operate if no improvement in nerve function has become apparent Our cases follow

1 Operation eight weeks—liberation of nerve from callus, excision ridge of bone Recovery

2 Operation forty days—nerve suture and bone suture Infection Failure

3 Operation ten weeks—musculo-spiral and median paralysis—fracture of humerus at junction of middle and lower third, fracture both bones of forearm, middle third Long operation—nerve suture of both Died just at end of operation Autopsy showed status lymphaticus

4 Musculo-spiral paralysis noted three days after admission Gradual improvement Spontaneous recovery

5 Fracture of humerus and both bones of forearm same side Also Potts fracture Retused operation Paralysis still present at three months

Any fracture of the shaft that permits of angulation after five weeks, I have classified as delayed or slow in union Six of these were present, five of these six were transverse fractures of the shaft Four were well united at the end of ten to twelve weeks Two continued as fibrous or non-union Both were cases of multiple fractures and very sick at the outset of their treatment One disappeared from observation One was operated on and showed a real inter-position of muscle tissue The bone ends were freshened, good alignment secured and held by kangaroo tendon No union resulted Seven months later she was operated on at another hospital and the kangaroo tendon was still clearly present An inlay graft was done and four months later no union was present It is interesting to consider possible causes for delayed or non-union other than purely mechanical causes, but the problem of bone metabolism still needs enlightenment We have carefully checked an appreciable number of fracture and osteomyelitic cases as to their phosphate and calcium blood content, but up to the present time have gained no therapeutic indications from it

Treatment—At present we treat all fractures of the humerus above the lower end in traction and suspension In fractures about the upper end we try to attain maximum abduction and external rotation largely because of the soft tissue injury and potential dis-

ability therefrom. In fractures of the shaft we use a position of 90 degrees abduction with forearm perpendicular to the bed. The suspending hammock for the arm itself is frequently reinforced on the inside with heavy felt. The outrigger for traction is always carried farther out from the side of the bed than in the high fractures so that when the patient moves in bed, he moves with the arc of a wider circle and thus minimizes any motion at the site of fracture. If union seems slow we try to hasten it by moderate manipulative irritation at the site of fracture. We believe traction suspension treatment to be the best treatment for fractures about the upper end of the humerus, we also believe it to be a very superior type of treatment for fractures of the shaft. It is comfortable to the patient, it reduces and aligns fractures, it gives maximum consideration to the maintenance of good circulation by encouraging movement in adjacent joints.

Fractures of the humerus at the lower end may well be a source of worry to all of us. Generalization is dangerous, but brevity at this time is imperative. In general we expect

good results in simple fractures of either condyle by treatment in acute flexion. In the supra-condylar fractures individualization is necessary and a choice must be made between the various right angled gutter splints, moulded plaster splints and such other retentive splints as appeal to the surgeon in charge. In those fractures which T and Y into the joint or present comminution along with these features the utmost ingenuity must be used to devise the proper splinting dressing. The maintenance of function in the joint by early motion must be the prime consideration. Too often however, early optimism must give way to discouragement as new bone continues to form from capsular or periosteal fragments and the initial result as to function becomes increasingly more limited. Possible ankylosis must always be borne in mind and the patient's occupation and choice must be a consideration in our own choice of treatment. No type of fracture better illustrates that axiom that applies to all fractures that even the most conscientious and well chosen treatment may result in dissatisfaction to patient and surgeon alike.

## SOME PRESENT-DAY TENDENCIES OF THE PRACTICE OF MEDICINE\*

By E C REIFENSTEIN, M.D.,

SYRACUSE N. Y.

**T**HIS Academy was formed in 1894. It has as its objects: (1) The cultivation and advancement of the science and art of medicine, (2) The promotion of public health, (3) The maintenance of the honor, character and interests of the medical profession.

The second object, the promotion of public health, is being successfully accomplished at the present time by our efficient Public Health Department, and therefore I shall not have anything to say with reference to it, but shall confine myself to the other two objects of the Society.

It is my purpose to review the present day tendencies of the practice of medicine as they are related to, and affect each member of the society individually. In so doing these tendencies must naturally influence to a certain degree the activities of the Academy.

At the start, it is well to point out certain evident lines of endeavor and to call attention to certain conditions, obstacles and handicaps of the practice of medicine.

It was not long ago when all that was considered necessary to practice medicine was a few years study with some reputable physician. Very

careful attention at that time was paid to the bedside instruction obtained. Then medical colleges and universities took up this important task, and ever since there has been a gradual increase in the requirements and standards so as to better prepare young men and women for the very important life work—The Practice of Medicine.

During this period there have been great strides made in the science of medicine so that the science today is more a science than ever before. Great discoveries in the laboratory as related to bacteriology, pathology, physiology and chemistry have given to the fortunate students of this period knowledge which has served as a working basis of inestimable value. During this time great emphasis has been laid, and rightly so, upon the necessity of acquiring these new facts as brought out from the laboratories.

Various methods of imparting this knowledge have been carefully studied and improved upon. Different methods of studying clinical medicine in the ward and at the bedside have been considered, with gradual improvement in the character of the instructions given, so that the prospective practitioner as he passes through the medical school acquires many facts related to the science both in laboratory and in the ward.

\* Delivered before the Syracuse Academy of Medicine, January 15, 1924.

Some days the entire time is spent in the ward discussing some phase or problem as it relates to the known facts in the different departments of medicine. This method of instruction is extremely important and valuable, but there is still missing an important part of the instruction before it can be said with positiveness that a person is fit to practice medicine.

The science of medicine as studied experimentally in the laboratory and in the wards, with great benefit to mankind, should be encouraged. It requires a special type of mind, and the need of this very important line of endeavor is so great that all of us should urge young men, whenever we see them so inclined to take up this field of work. Under the present plan of education, after one has passed through the medical school and has had the opportunity of thorough preparation in the science of medicine, the student then serves one or more years in some hospital. During this period he has occasion to see many of the facts as related to the science demonstrated in patients, and he gradually increases his knowledge from the various phenomena which are exhibited. Finally, he leaves the hospital full of hope and confidence and with great expectations, that now he is ready to practice medicine.

In a short time he comes to the realization of a very important fact, that there is something definitely missing in his armamentarium, and that there is evidently another side to the practice of medicine, of which he has heard but little or at least to which very little attention has been called, and this is the Art of the Practice of Medicine.

The late Dr. Elsner, when he started his lectures, would give the following definition of the practice of medicine:

"It is the science and art of medicine, and the greater of these is the art."

All of you who knew him well can subscribe to this statement.

When one attempts to describe what constitutes the art he finds himself utterly incapable of expressing all its various phases. The art should be cultivated. Attention should be called to it early in the medical student's life instead of leaving him to acquire it in various ways after graduation.

It is not my purpose to minimize in any way the efforts made to impart the knowledge related to the science. I believe that this is very thoroughly done at present so that it is not so much the science that is at fault or insufficient, which enables so many cults to spring up, but it is the lack of thorough appreciation of the art of the practice of medicine.

The known facts of medicine are available to all of us. The mere possession of this knowledge is not sufficient to practice medicine. A few

examples to illustrate the distinction between the science and the art may not be amiss. Take for instance a patient who requires catheterization. There are certain symptoms and signs discovered which indicate that the patient has a distended bladder. Two practitioners arrive at the same conclusion. One will immediately, after sterilization, pass a catheter and relieve the bladder. The second will observe the rules of asepsis, but will first, before passing the catheter, use a small percentage of local anæsthetic, and without any discomfort to the patient, accomplish the same result. Those of you who have ever had this experience, will soon discover the difference between the physician who has art and the one who is filled with science without any art.

Similarly one may observe in cystoscopic examination how in some instances great care and gentleness is practiced, in other instances this very distressing examination is done with very little regard, apparently, for the sensibilities of the patient. In the latter type it is "just a cystoscopic examination", in the other it is the patient suffering. This distinction, to my mind, illustrates clearly the advantage of the cultivation of the art.

I recently read a criticism of doctors which I will take the liberty to quote: "Why do doctors so often make mistakes? Because they are not sufficiently individual in their diagnosis or their treatment. They class a sick man under some given department of their nosology whereas every invalid is really a special case, a unique example. How is it possible that so coarse a method of sifting should produce judicious therapeutics? Every illness is a factor invariably complex—the individual, that is to say, who is suffering from it, so that the result is a special problem demanding a special solution, the more so the greater the remoteness of the patient from childhood or from country life. The principal grievance which I have against these doctors is that they neglect the real problem, which is to seize the unity of the individual who claims their care. Their methods of investigation are too elementary. A doctor who does not read you to the bottom is ignorant of the essentials."

It is well for us to take this criticism to heart and ponder over the same. We will do well if we begin within ourselves to correct certain tendencies of practice which we have been compelled to follow, either because we have allowed the public to lead us along with these tendencies or because we have not ourselves seen the light of modern medicine and its possibilities. There is a large percentage of individuals who class our practitioners as mere dispensers of drugs, in fact it was the custom, and is yet the custom in many instances, for a physician to carry a stock of drugs almost equal to that carried by the corner drug store. What is the result? The individual is sick, he thinks in terms of drugs

for immediate relief. He, with his self-made diagnosis, seeks a physician. The physician, not on his guard, or unwilling to spend the time, takes this diagnosis and then considers that his chief function is the distribution of two or three packages or bottles of medicine, and the individual considers the transaction closed. He pays dearly for this transaction in a sense, and the physician who has spent years in study, who knows medicine, has not even had a chance to exercise the knowledge or his art.

How frequently we hear the diagnosis of the "grippe," or "rheumatism," or "sluggish liver," or "nervousness," all of which truly express an actual ignorance of the state of the individual. It is an easy way to label an individual who is sick with one of these terms, and many times a short cut to a diagnosis.

I do not blame the medical profession alone for this state of affairs, the public is also at fault because it has been educated for many years to expect this kind of service from our profession. It is up to us to educate the public to the idea that we are no longer "purveyors" of medicine but rather that our chief function is to diagnose the sick individual and then to apply certain therapeutic agents, whether mental healing, drugs, massage, mechanotherapy, surgery, electricity or any other remedy which shall relieve suffering.

What group of men is better trained to diagnose the complaint of an individual than that of our profession? A little more attention to the art is very helpful. I am certain that when all of the profession pay attention to diagnosis and also to the application of this art, better therapeutic results will be obtained and our profession more highly respected.

It may be well to call attention to certain other phases of the art, particularly the art of history taking. This is a tedious job sometimes, but with experience it does not take very long to acquire the essential points. The history need not be a long and extensive one, in fact, some of the best histories I have ever read were so condensed as to be easily placed upon a small card. Some physicians state that they have not the time to write a history, which perhaps is true under present practice, but I am confident that if this plan was universally followed the physician would be more highly respected, and that the work would be more evenly divided, and that all physicians would have time to do this very important part of the work.

A criticism frequently made is that doctors are not usually very specific as to how their directions should be carried out. They are given verbally to the patient sick in bed, and then half an hour after the physician has departed the patient is at sea as to what directions were given. A few minutes time with pencil and paper would help

the patient beyond question, and incidentally would elevate the standing of the physician in that family. In many instances the diagnosis can be made alone from the history, but never is the service of the physician properly rendered until he has examined the patient. Here again we hear serious criticisms of our profession. Patient after patient makes the rounds of physicians without ever receiving even a superficial examination. The examination of the patient is an art, cultivated by practice. Each individual is a law unto himself, and only by having the opportunity to observe the normal with its many variations is one able to evaluate certain deviations. Therefore, the lack of knowledge of the variations of the normal, in many instances, has been responsible for serious errors in judgment. There is one thing that our profession is best qualified to do, and that is to make a complete physical examination. It is a hopeful sign that more attention is being given to this part of our practice. Insurance companies are calling attention to the necessity for a complete physical examination at periodic intervals. Here is a great opportunity for us. Of course, there is an art in the application of physical examination. Inspection is an art. Invaluable information can be obtained by careful inspection. Sometimes the diagnosis is established from the evidence obtained from inspection. The proper light as an aid is not fully appreciated. The art of palpation so that our finger tips have eyes, together with the careful and painstaking methods of percussion and auscultation are only acquired by continual practice. It should be the earnest endeavor of every physician to try to improve himself in this very important and very necessary part of his service to the suffering individual. Far better is it to make one hundred physical examinations with normal findings than to miss the one who has an incipient lesion, the discovery of which would lead to the proper cure by its early recognition.

Now that the history has been taken and an examination made, in many cases a diagnosis is arrived at. At least confidence in the physician has been inspired, so that additional data referable to the history is frequently freely given by the patient at this time, and this data relates to fear. Many patients will give a rather clear cut history at times of a serious illness which after careful physical examination is not substantiated. Then one will try to discover where the fault lies, and another cross-examination of the patient will bring forth the information that the underlying cause of the complaint is a morbid fear of some definite organic and serious ailment. The reassurance to the individual that he is normal as far as the physical examination is concerned, is the greatest medicine that the individual can possibly have. The relief from symptoms starts almost at the moment that such information has been given.

There are many individuals who are constantly seeking such advice. They value it higher than any other remedial agent. There is no question at all but there are cases which start with fear as the basis of the trouble which are so changed by the unnecessary administration of drugs that it becomes difficult to estimate which is the cause and which is the effect. This fact may explain the success of many of the cults now in existence and from which many sufferers seek relief. In order to elicit fear from the patient it is necessary that one have his confidence.

Nothing inspires greater confidence than the earnest, conscientious, and sympathetic physician who is desirous of doing all that is in his power to do to relieve the unfortunate individual.

To appreciate the value of confidence or faith in removing fear it seems to me that the physician first must have within himself faith that he is a part of a profession which is especially favored by the Divine Master because He was the first great physician. The physician must be familiar with the teachings as given by Christ. There is a wonderful opportunity for our profession to embrace some of His teachings and to practice some of His teachings. Cultivate the spirit of brotherly love towards all mankind, especially towards the members of the profession, "with charity to all and malice towards none."

I recently read a quotation which impressed me most strongly in this respect. "To me, the ideal doctor would be a man endowed with the profound knowledge of life and of the soul, intuitively divining any suffering or disorder of whatever kind, and restoring peace by his mere presence. Such a doctor is possible, but the greater number of them lack the higher and inner life. They know nothing of the transcendent laboratories of nature, they seem to me superficial, profane, strangers to the divine faith, destitute of intuition and sympathy. The model doctor should be at once a genius, a saint and a man of God."

This is unusual, but a very high ideal as to the status of the physician. Many physicians fail to appreciate the importance of fear. They consider that the removal of some pathological organ, such as an appendix, or a gall bladder, or tonsils will relieve the unfortunate sufferer. The patient is told "now that the cause has been removed, go and get well," with no specific directions as to how to live so as to adjust his nervous system to the strain incident to the every day life, with no attention to diet or to the regulation of habits.

The surgeon, who today is considered to be a therapeutic agent, it would seem, is, in many instances responsible for sending such patients out when he has the greatest opportunity of helping many and incidentally preventing many so-called "secondary" operations, by giving very timely advice instead of, as many do, considering

the case closed as soon as the sutures are removed.

This is a serious criticism of our profession and it is not always necessary that these cases should be referred to an internist, but that the surgeon as well as the rest of the profession should be familiar with the rules as to the regulation of the activities of the body.

With full appreciation of the importance of diagnosis as the first aid in the relief of the sick individual, State Medicine has gradually increased its field of usefulness as an aid to physicians by supplying laboratory facilities and also state consultants. Fear has been expressed by some physicians that the state was taking away from them some work which they ought to have. To my mind the work the state is doing is an asset and a help. One part which she cannot take but which she is desirous of encouraging is the art of diagnosis and practice.

In the same way various groups of physicians throughout the country, realizing the great importance of diagnosis, have attempted to improve the quality and the character of diagnosis given to certain individuals. There is no doubt that a certain percentage of patients require the opinion of more than one man before the final diagnosis can be arrived at, but again, by far the greater percentage of individuals who suffer can be correctly diagnosed by their regular physician, provided attention to the science and art of medicine is given by him.

Another serious criticism which reflects upon the high standing of our profession is that which one occasionally hears from laymen, in that they will not reveal to the doctor all they know about themselves because they think the doctors cannot keep a secret. They are afraid to repose their secrets with men, when for instance, at a public place they hear their secrets become common property. It is well to state that this is not a general practice, but an occasional occurrence of this kind does irreparable damage to our profession, and we all, in consequence, suffer for it. It is not amiss to remind you of the sacred oath which you took at your graduation.

"Whatever in connection with my professional practice or not in connection with it I see or hear in the life of men which ought not to be spoken of abroad I will not divulge as reckoning that all such be kept secret."

It is true that the laymen consider that we are discussing names of patients when they hear us discussing cases in public, and perhaps the public has been a little unjust to us in this respect, but the mere fact that the criticism is abroad is enough for us all to be especially guarded as to what we discuss in public places.

Another serious handicap in practice is as follows. Cases are seen where one is desirous of having proper massage or electricity given. At present this work is done by individuals who in

many instances are not familiar in any sense with the various changing moods of the patient. The same rule is applied to each patient who needs massage regardless of the particular needs of the sick individuals. This academy would do well, it would seem to me, to consider the advisability of having certain individuals registered with the secretary, and if he became too busy, a paid assistant secretary might well function in this capacity, so that whenever a physician appreciates the necessity of massage, he can refer to the secretary for information as to the list of those who are competent to give this form of treatment. In the same manner the medical profession should encourage co-operation with the clergy. There are many sick unfortunate individuals who are sick mentally. The combined efforts of the clergyman or priest whose work is closely identified with ours, and a physician, will many times be able to help the unfortunate sufferer and enable him to lose his morbid fears. I have great confidence in the wonderful aid which certain clergymen can give us.

In like manner I have found it a handicap in certain instances, when I have felt a patient needed complete rest and have secured their co-operation to go to a hospital for rest, to then find that the hospital was even more noisy and full of confusion than the home. Hospitals as

they are planned at the present time, seem to be primarily planned to meet surgical requirements. Little attention is given to the needs of patients who suffer from many of the other disorders, relieved either by rest in bed, proper diet, massage, baths or mechanotherapy. Large hospitals in other cities are so equipped, but unfortunately, here in Syracuse, we who wish to use this means of practice find the existing conditions to be a serious handicap. It may be to the advantage of the Academy, through its Hospital Committee, thoroughly to consider this important necessity in improving the medical practice as it is at present in Syracuse. As was mentioned above, I feel that this Academy should aim for higher things, that it should carefully consider having a paid assistant secretary. In order to do this its income should be increased. There are many other places where a paid secretary could be of service to the members of this Society. In addition, it would seem to me wise for the Academy in its thirtieth year to consider most seriously some permanent meeting place where the activities of this Society might be enlarged upon.

It is my hope, therefore, that by improving the general character of the practice of medicine in Syracuse, the Syracuse Academy of Medicine will maintain such a place as to be second to none in this country.

## THE VALUE OF THE EDUCATIONAL CAMPAIGN IN PROMOTING THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS\*

By HARRY GOLEMBE, A B, M D

LIBERTY, N Y

**E**DUCATIONAL campaigns in medicine during the past two decades seem to have been the method of choice in reaching the lay public in the battle against disease. This is very well evidenced by the splendid work done by the National Tuberculosis Association, *The Journal of the Outdoor Life* (a lay journal for the tuberculous patient), the campaign of publicity conducted by the American Cancer Association, and now the new national lay journal, *Hygeia*, published by the American Medical Association.

There is hardly a state in the Union where various health and nursing bureaus have not been formed to carry the gospel of good health out to the people. Pre-natal clinics, district nurses, and even health demonstrations on a large scale such as are being carried out in Framingham and in Syracuse under the Milbank Foundation are scattered throughout the breadth of the land. With the advent of the radio, health talks are being broadcast by various city and state departments of health.

Can anyone doubt the value and importance of this work or think long as to why it has developed in so short a time to such tremendous proportions? Physicians and workers interested in public health problems have long realized the great role played by the educational campaign in combating disease and they are using every conceivable method in reaching the lay public directly.

This, to my mind, is only one-half of the work. That it has been well done no one can deny. The other half of the work that has not been well done and which all educational campaigns seem to have left out entirely, or at the most to have given but a small insignificant place, is the education of the medical public itself.

My own observations have been practically confined to the field of tuberculosis, where perhaps more has been done along these lines than in any other branch of medicine. Certainly a great deal of good has been accomplished by the systematized campaigns among the general public carried out under the auspices of the National Tuberculosis Association. Here the opportunity of reaching the general medical public and broad-

\* Read at the Annual Meeting of the Third District Branch of the Medical Society of the State of New York, at Loomis, October 9, 1924.

casting advice as to diagnosis, management, and treatment of tuberculosis has surely been a good one. Sanatoria are scattered all over the country, but it is only the exceptional one, such as the Adirondack Cottage Sanatorium (Trudeau) or the Colorado School of Tuberculosis at Colorado Springs that is making any special effort to teach tuberculosis to the general practitioner. Unfortunately these schools are small and have attracted only those physicians who are desirous of specializing in tuberculosis. The average general practitioner still remains as ignorant of tuberculosis as he has been in the past. This is still an open field for a great deal of good work in the fight against the inroads of the tubercle bacillus. It is one that demands vigorous and concentrated efforts, for the average physician hates to admit his shortcomings, especially when it pertains to such a common disease as tuberculosis.

During the past year I have had ample opportunity to observe a large group of patients sent to a health resort for pulmonary tuberculosis. These cases have been, in the main, under the care of the average general practitioner. It is my purpose to analyze these cases and arrange them under various groups so as to bring out the value of early diagnosis on prognosis, the importance of early sputum and X-ray examinations. I will not attempt to teach the general practitioner the proper method of examining a chest in order to make an early diagnosis. This has been well done in the past by means of brilliant papers written by leaders in the tuberculosis movement. In light of my experience this has certainly proven to be the wrong method of attack in reaching the average medical man. You cannot teach a man who is not interested in tuberculosis *per se* how to distinguish various types of rales, differences in physical findings, and other fine points no matter in how flowery a language you write your descriptions. That is a phase of the tuberculosis problem that we must tackle in the medical schools where the teaching of tuberculosis has been badly neglected. It is the very exceptional school that gives its undergraduates a thorough training in the diagnosis and treatment of tuberculosis. But we can teach the general man "to play the game safe", we can teach him by means of an educational program to think of tuberculosis early in the presence of such symptoms as cough, expectoration, fever, sweats, malaise, hemoptysis, hoarseness, loss of weight, pleurisy, ischio-rectal abscess, and even in so called "stomach trouble", we can teach him to be just as cautious in the presence of possible tuberculosis as he has learned to be with other diseases in the modern practice of medicine. For example, let us see what has been accomplished in diphtheria since the discovery of the diphtheria bacillus and diphtheria antitoxin and in the management of fractures since the X-ray

has assumed its proper place in the practice of medicine. No man, no matter how keen a diagnostician he considers himself, will treat a child or even an adult with a sore throat without taking a throat culture at the first examination, and not infrequently, even if he is absolutely certain that diphtheria is not present, he will go as far as giving a prophylactic dose of diphtheria antitoxin. Yet how many of these same men will treat a case having a persistent cough for many, many months without even thinking of doing such a simple thing as having the sputum examined or a radioscopic study of the chest made. If one of his sore throat patients, in whom he had neglected to be cautious, died of diphtheria, just think of the hue and cry that would be justifiably raised, let alone the possibility of giving up practice and a suit for malpractice. While on the other hand if one of his chronic coughers in whom he has been just as neglectful is suddenly pronounced a hopeless consumptive after many months of observation, nobody looks upon it as extraordinary and malpractice is not even considered. The same analogy can be drawn to the modern management of fractures since the advent of the X-ray.

If this study will help in awakening the general practitioner to the importance of early diagnosis, the importance of sputum analysis, and the importance of X-ray examination, then its purpose will certainly have been accomplished.

The cases that I have selected for this study are all private patients and have been under my care during the past year. I have included only those in whom a definite diagnosis of pulmonary tuberculosis was made and I may at some later date, in a separate study, discuss those cases sent here for tuberculosis who proved to have some other pulmonary lesion.

In Chart One I have tabulated the cases according to the stage, activity and prognosis on the first examination. This chart proves most instructive and enlightening. Of a total of 145 cases, 108 or 74.5 per cent proved to be cases of far advanced pulmonary tuberculosis and in practically the same number, 70.4 per cent, the original prognosis was doubtful, unfavorable or hopeless. These figures certainly speak for themselves. They tell us that an overwhelming majority of this group of patients were given an opportunity to carry out proper measures leading towards ultimate recovery only too late. In comparing these figures with chart number two we see another very significant fact, namely, that a diagnosis of pulmonary tuberculosis was not made until at least six months had elapsed from the time tuberculosis first exhibited itself as evidenced by the history in over 63 per cent of the cases. And were we to include in this group those in whom a diagnosis was not made at all before coming to the mountains, we again have

the very striking figure of 73.8 per cent. In other words only one patient in four was fortunate enough to have a diagnosis of pulmonary tuberculosis made within a reasonable time, inside of three months, thus giving that patient a better and a quicker opportunity to carry out the necessary measures leading to ultimate recovery. These two sets of figures certainly parallel one another. Can anyone long question why only one patient in four is not far advanced and has a good prognosis for ultimate recovery when three-quarters of the patients are kept at their ordinary work for at least six months before a diagnosis of their true condition is made and proper treatment instituted? Many explanations for such a state of affairs presented themselves to me in going over these cases. I will discuss each one of them separately and endeavor to show their importance and how publicity and education carried out by such organizations as the National Tuberculosis Association, various county tuberculosis societies and possibly state health departments among the general medical public, will prove beneficial in hastening the early diagnosis of tuberculosis.

1 *Sputum Analysis*—When Koch discovered the tubercle bacillus he gave to medicine a means whereby tuberculosis could be diagnosed with absolute certainty. It is almost an axiom that the presence of tubercle bacilli in the sputum is proof conclusive of pulmonary tuberculosis. Although this fact has been known for over forty years, is it not surprising and appalling that in over 90 per cent of this group of cases the physician in charge neglected to have a sputum analysis made within three months of the onset of symptoms? It is more surprising when one is told that most of these patients came from New York City where Department of Health stations for the collection of specimens for examination are scattered all over the city and such examinations are made without charge. Does not this fact alone open up room for a good deal of improvement? Publicity carried out along this direction alone will play a big part in promoting early diagnosis. The general practitioner should make it a rule, as he does with throat cultures in sore throats, to have sputum analyzed in all cases having symptoms or signs pointing to pulmonary disease regardless of whether or not he believes it to be tuberculosis.

2 *Röntgenological Examination of Chest*—The discovery of the X-ray gave to the study of tuberculosis a sign which is almost second to none in the diagnosis of chest pathology. A positive diagnosis of pulmonary tuberculosis by means of an X-ray plate is practically equal in importance to the finding of tubercle bacilli in the sputum. And yet in only ten of this group of cases, or less than 7 per cent, was this well recognized method of diagnosis resorted to within three

months of the onset of the disease. Radioscopic units are now at hand wherever physicians are located. For the poorer patients most out-patient departments are either equipped with machines or have connections whereby radiological study can be made at minimum cost to the patient. With such a sure method of diagnosis available to all physicians there is no excuse for great delay in making a proper and early diagnosis of pulmonary tuberculosis.

3 *Hemoptysis*—Hemoptysis occurred as a first symptom of tuberculosis in fifteen patients of this group. Despite this a diagnosis of pulmonary tuberculosis was not made in ten of these cases within six months of the onset of this very important symptom. Tonsilectomies were done (in vain) in four cases in order to stop the hemorrhage. Clinical experience has taught us that a very safe rule to follow is to treat all cases of hemoptysis, at least in young adults and those in whom cardio-vascular disease can be ruled out, on the basis of pulmonary tuberculosis until otherwise proven. Workers in tuberculosis have always looked upon hemoptysis as a blessing in disguise when coming as a first symptom. For if any one symptom of tuberculosis frightens both physician and patient alike into immediate action and causes them to institute proper rest therapy at once, that symptom is hemoptysis. Regardless of the physical findings, hemoptysis should be considered as due to tuberculosis, with the exception as mentioned above, and other rare conditions such as hereditary hemoptysis referred to by Libman and Ottenberg,<sup>1</sup> until exhaustive study and watching of the case proves the opposite. Operative interference such as tonsilectomy is gross mistreatment in the vast majority of cases of hemoptysis and is therefore inexcusable.

4 *Pleurisy with Effusion*—Acute pleurisy with effusion occurred in nine cases of this group at least one year before a diagnosis of pulmonary tuberculosis was made. The fact that a majority of all cases of pleurisy with effusion are due to tuberculosis is of such great importance that it should be made known to all practitioners. Osler<sup>2</sup> quotes many authorities who have followed their cases for a number of years subsequent to the original diagnosis of pleurisy with effusion in confirmation of this point. Is it not a significant fact that all of these nine patients when first seen by me were far advanced cases of tuberculosis? Can anyone doubt that some of these patients would have been helped to ultimate recovery had they received the benefit of the doubt at the time they were ill with pleurisy and had follow-up treatment on the basis of pulmonary tuberculosis been immediately instituted? In my own sanatorium experience and also in

private practice it was just those patients who were properly advised at the time of their pleurisy and given correct rest therapy on the basis of pulmonary tuberculosis who made good recoveries and were able to return to gainful occupations. Certainly their chances for remaining so are far better than those who were not treated along these lines. General practitioners should be impressed with the fact that pleurisy with effusion is not just "plain simple pleurisy," but that it is in all likelihood only a manifestation of pulmonary tuberculosis which demands the same kind of treatment as does "ordinary" pulmonary tuberculosis.

**5 Ischio-rectal Abscess**—Careful history taking disclosed the fact that an ischio-rectal abscess occurred as the first sign of tuberculosis in seven patients. Not one of these patients connected this with their tuberculosis and apparently the physician under whose care they were at the time never thought of it either. Ischio-rectal abscess occurs as a complication of tuberculosis in a great many patients. In addition to the seven patients mentioned above, twenty-one other patients of this group developed an ischio-rectal abscess sometime in the course of their pulmonary tuberculosis. This manifestation of tuberculosis is probably the one that is least known to the average general practitioner and publicity of this fact among medical men should certainly prove of great value. In this connection I am reminded that Dr. Maurice Fishberg used to teach his students, that in the presence of an ischio-rectal abscess or an anal fistula, the chest should always be examined for pulmonary tuberculosis regardless of whether or not the patient has symptoms pointing to pulmonary disease.

**Comment** I have attempted in this paper by means of a clinical report to bring out the value of the educational campaign in promoting the early diagnosis of tuberculosis. By analyzing a large number of cases and arranging them into various groups, I have shown how a better understanding of the facts disclosed by this study would undoubtedly have helped a greater percentage of this group of patients to ultimate recovery.

To those of us who are doing tuberculosis work the facts as illustrated by this group of patients are only too well known. The problem is to bring the benefit of this knowledge home to the general practitioner. The only solution that I can see at present is the carrying out of an intensive educational campaign among the medical public as is being done by the U. S. Public Health Service in its cooperative work with State Departments of Health in their fight against the spread and for the proper management of syphilis and gonorrhea. We cannot ask busy practitioners to return to school to learn all over again

the physical diagnosis of the chest in tuberculosis, nor to study again the many manifestations of pulmonary tuberculosis, but we can by means of bulletins, case reports, clinics, lectures, and health demonstrations directly among the medical public, teach them to "play the game safe" and to resort to other methods of diagnosis such as sputum analysis and X-ray examination earlier in the course of the patient's illness. Tuberculosis is just as important a disease from the public health standpoint as are gonorrhea and syphilis, and there is no reason for neglecting to do for tuberculosis what is being done for these two diseases. The value of the rest regime in tuberculosis has been proven beyond question, but statistics have shown us that the more lasting results are obtained in the less advanced cases. Let us profit by this experience and do our utmost to bring home the importance of early diagnosis to the general practitioner by every means at our command. If necessary let us teach him to be overcautious. For to err on the safe side will certainly not be harmful to the patient, while to err where "safety first" might have proven beneficial to the patient, is almost inexcusable.

# CHART ONE

## EXTENT OF TUBERCULOSIS, ACTIVITY, AND PROGNOSIS ON FIRST EXAMINATION

		No. of Patients	Per Cent
1 Stage	Minimal	10	6.9
	Moderately Advanced.	27	18.6
	Far Advanced	103	74.5
	Total number of cases	145	
2 Activity	Slight or none	11	7.5
	Moderate	56	38.6
	Marked	78	53.9
	Total number of cases	145	
3 Prognosis	Excellent	10	6.9
	Favorable	33	22.7
	Doubtful	54	37.3
	Unfavorable	27	18.6
	Hopeless	21	14.5
	Total number of cases	145	

# CHART TWO

## LENGTH OF TIME AFTER ONSET OF PULMONARY TUBERCULOSIS BEFORE DIAGNOSIS WAS MADE

	No. of Patients	Per Cent
1 Within three months	38	26.2
2 Within six months	55	37.9
3 Within nine months	37	25.6
4 Diagnosis first made in Liberty	15	10.3
Total number cases	145	

the very striking figure of 73.8 per cent. In other words only one patient in four was fortunate enough to have a diagnosis of pulmonary tuberculosis made within a reasonable time, inside of three months, thus giving that patient a better and a quicker opportunity to carry out the necessary measures leading to ultimate recovery. These two sets of figures certainly parallel one another. Can anyone long question why only one patient in four is not far advanced and has a good prognosis for ultimate recovery when three-quarters of the patients are kept at their ordinary work for at least six months before a diagnosis of their true condition is made and proper treatment instituted? Many explanations for such a state of affairs presented themselves to me in going over these cases. I will discuss each one of them separately and endeavor to show their importance and how publicity and education carried out by such organizations as the National Tuberculosis Association, various county tuberculosis societies and possibly state health departments among the general medical public, will prove beneficial in hastening the early diagnosis of tuberculosis.

1 *Sputum Analysis*—When Koch discovered the tubercle bacillus he gave to medicine a means whereby tuberculosis could be diagnosed with absolute certainty. It is almost an axiom that the presence of tubercle bacilli in the sputum is proof conclusive of pulmonary tuberculosis. Although this fact has been known for over forty years, is it not surprising and appalling that in over 90 per cent of this group of cases the physician in charge neglected to have a sputum analysis made within three months of the onset of symptoms? It is more surprising when one is told that most of these patients came from New York City where Department of Health stations for the collection of specimens for examination are scattered all over the city and such examinations are made without charge. Does not this fact alone open up room for a good deal of improvement? Publicity carried out along this direction alone will play a big part in promoting early diagnosis. The general practitioner should make it a rule, as he does with throat cultures in sore throats, to have sputum analyzed in all cases having symptoms or signs pointing to pulmonary disease regardless of whether or not he believes it to be tuberculosis.

2 *Röntgenological Examination of Chest*—The discovery of the X-ray gave to the study of tuberculosis a sign which is almost second to none in the diagnosis of chest pathology. A positive diagnosis of pulmonary tuberculosis by means of an X-ray plate is practically equal in importance to the finding of tubercle bacilli in the sputum. And yet in only ten of this group of cases, or less than 7 per cent, was this well recognized method of diagnosis resorted to within three

months of the onset of the disease. Radioscopic units are now at hand wherever physicians are located. For the poorer patients most out-patient departments are either equipped with machines or have connections whereby radiological study can be made at minimum cost to the patient. With such a sure method of diagnosis available to all physicians there is no excuse for great delay in making a proper and early diagnosis of pulmonary tuberculosis.

3 *Hemoptysis*—Hemoptysis occurred as a first symptom of tuberculosis in fifteen patients of this group. Despite this a diagnosis of pulmonary tuberculosis was not made in ten of these cases within six months of the onset of this very important symptom. Tonsilectomies were done (in vain) in four cases in order to stop the hemorrhage. Clinical experience has taught us that a very safe rule to follow is to treat all cases of hemoptysis, at least in young adults and those in whom cardio-vascular disease can be ruled out, on the basis of pulmonary tuberculosis until otherwise proven. Workers in tuberculosis have always looked upon hemoptysis as a blessing in disguise when coming as a first symptom. For if any one symptom of tuberculosis frightens both physician and patient alike into immediate action and causes them to institute proper rest therapy at once, that symptom is hemoptysis. Regardless of the physical findings, hemoptysis should be considered as due to tuberculosis, with the exception as mentioned above, and other rare conditions such as hereditary hemoptysis referred to by Libman and Ottenberg,<sup>1</sup> until exhaustive study and watching of the case proves the opposite. Operative interference such as tonsilectomy is gross mistreatment in the vast majority of cases of hemoptysis and is therefore inexcusable.

4 *Pleurisy with Effusion*—Acute pleurisy with effusion occurred in nine cases of this group at least one year before a diagnosis of pulmonary tuberculosis was made. The fact that a majority of all cases of pleurisy with effusion are due to tuberculosis is of such great importance that it should be made known to all practitioners. Osler<sup>2</sup> quotes many authorities who have followed their cases for a number of years subsequent to the original diagnosis of pleurisy with effusion in confirmation of this point. Is it not a significant fact that all of these nine patients when first seen by me were far advanced cases of tuberculosis? Can anyone doubt that some of these patients would have been helped to ultimate recovery had they received the benefit of the doubt at the time they were ill with pleurisy and had follow-up treatment on the basis of pulmonary tuberculosis been immediately instituted? In my own sanatorium experience and also in

duration, deflection of septum to left with adhesion to middle turbinate. Submucous resection of septum and separation of adhesion, followed by complete relief from headache.

Mr G M, age 23. Bilious attacks off and on all his life. For fifteen years has had unilateral headache, growing gradually worse until now it occurs daily. It comes on at eleven o'clock and increases in severity until bedtime. He is frequently obliged to give up his work in the afternoon and go to bed. Headache is worse in the summer time. Pain is felt over the left side of the bridge of the nose, over the left supra-orbital region, and in the left temple. It is rarely accompanied by vomiting.

*Examination*—Nasal mucosa and turbinates normal. Septum deflected to the left, deviation beginning half-inch above the floor of the nose and extending above the left middle turbinate, which is firmly adherent to it.

*Operation*—A submucous resection was done, removing the septum to a point above the middle turbinate and back almost to the naso-pharynx. The middle turbinate was then separated from the septum. From the time of operation to the present, the patient has not had a single headache.

*Case 3*—Dull pain over left eyebrow. Long adhesion between inferior turbinate and septum. *Operation*. Cure of pain.

Mrs H S, 25 years of age. Good family history. Tonsils were removed one month ago for recurrent quinsy. For five or six years she has suffered from a dull supra-orbital pain, sharply localized, coming on every morning and lasting one or two hours.

*Operation*—A long adhesion between left inferior turbinate and septum was removed by a submucous resection of septum. No headache since operation.

#### B VACUUM HEADACHES

To Sluder of St. Louis is due the credit for first accurately describing this condition, as well as the syndrome of nasal ganglion neuroses.

Vacuum frontal headache is difficult to diagnose. The patient has a low grade constant headache which is made worse by using the eyes for near work, such as reading, and which glasses or eye treatment do not relieve. The pain is usually worse in the morning. In this type of case, we find a tender point at the upper and inner angle of the orbit (Ewing's sign). The pain experienced on using the eyes is due to traction exerted by the pulley of the superior oblique muscle upon the sensitive floor of the frontal sinus.

Certain anatomical peculiarities may be factors in the production of vacuum frontal headaches, such as:

(1) Narrowing of the middle meatus due to thickening or deflection of nasal septum.

(2) Obstruction of the hiatus semilunaris (outlet of frontal sinus) by hyperplasia and enlargement of the bulla in front, or the processus uncinatus behind. This oedema of the middle meatus and hiatus semilunaris often follows the ordinary head cold.

Treatment consists in removing the underlying cause by the resection of the middle turbinate or hyperplastic tissue about the outlet of the frontal sinus, with or without a submucous resection of the septum. The relief afforded is usually prompt and gratifying.

#### C NASAL (MECKEL'S) GANGLION NEUROSES

The sphenopalatine ganglion, also known as Meckel's or the nasal ganglion, is situated in the sphenomaxillary fossa, close to the sphenopalatine foramen, in close proximity to the sphenoidal cavity. The symptoms of neuroses of this ganglion so closely resemble those of hyperplastic sphenoiditis that it is unnecessary to describe its symptom complex separately. In ganglion neuroses, the intra-nasal application of strong cocaine solution directly to the mucous membrane over the ganglion stops the pain temporarily, while in hyperplastic sphenoiditis this procedure fails to give relief.

II The inflammatory conditions producing headache may be divided into two main groups:

- (a) Hyperplastic ethmoiditis and sphenoiditis
- (b) Suppurative inflammation of the sinuses, either acute or chronic

#### A HYPERPLASTIC SPHENOIDITIS

Hyperplastic sphenoiditis occurs usually in conjunction with hyperplastic ethmoiditis. The symptom complex is somewhat as follows. The patient complains of a coryza, and, after a short interval, he experiences pain at the root of the nose, in the eye-ball region, upper jaw and teeth. This pain may extend backward to the ear and mastoid and downward into the shoulder, arm and fingers. Sluder has observed salivation, a perverted sense of taste (metallic) and scintillans. These headaches have been termed "lower half headaches." Examination of the sphenoidal region is difficult. The mucous membrane of the ethmoids and sphenoid is changed both in color and consistency. Usually it is necessary to rely upon the characteristic history and symptom complex in making a diagnosis rather than upon the appearance of the structures intranasally.

The following case, recently operated at the New York Eye and Ear Infirmary, illustrates this condition.

*Case 4*—Right sided parietal and occipital headache of three months' duration, caused by hyperplastic ethmoiditis and sphenoiditis with deflected nasal septum. Intranasal excision of ethmoids and sphenoid, submucous resection of septum. Relief of headache.

Mr H S, 37 years old. Has always had

## HEADACHE OF NASAL ORIGIN

By GERARD HUTCHISON COX, M.D., F.A.C.S.,

GLEN COVE, N. Y.

ONE of the complaints the practitioner of medicine is most frequently called upon to treat and one of the conditions most difficult to diagnose is headache. Headaches arise from many causes. Some of them are toxic or infectious, involving many organs, but probably most of them come from pathologic conditions of the nose and its accessory sinuses.

The proximity of the nasal sinuses to the cranial cavity and the fact that the same nerve, the trigeminus, supplies both the mucous membrane of the sinuses and the dura mater, explain the frequency of headache as a symptom of sinus disease and other nasal abnormalities.

The innervation of the nose for common sensation is derived from the ophthalmic and superior maxillary divisions of the trigeminal nerve. The lateral wall of the nasal fossa is supplied from several sources, including the upper posterior nasal branches from Meckel's ganglion, and the lower posterior nasal branches from the larger palatine nerve behind, and, in front, the external division of the nasal nerve and the nasal branch of the anterior superior dental, which also distributes twigs to the floor of the fossæ. The septum receives its chief supply from the naso-palatine nerve, supplemented by branches from Meckel's ganglion behind, and by the internal division of the nasal nerve in front. The mucous membrane lining the antrum receives filaments from the infraorbital nerve by means of its superior dental branches. The frontal sinus is supplied by twigs from the supra-orbital and the nasal nerves, the ethmoidal air cells, by minute branches from the nasal, and the sphenoid sinus, by filaments from the sphenopalatine ganglion.

We see, therefore, why in the case of frontal sinus disease, pain is referred to a point in the forehead over the anterior wall of the sinus, corresponding to the distribution of the supra-orbital nerve. In the same way, in case of the maxillary antrum, which, as we have just seen, is supplied by twigs from the intraorbital nerve, we can account for the pain being felt in the cheek and in the teeth. Hajek has suggested that there is set up a kind of neuritis of the nerve in question. However, when we try to explain why pain from disease of the sphenoidal sinus is usually experienced in the occiput, we fail to find any reason why sensory impulses coming from this particular sinus to Meckel's ganglion should be experienced as pain in the occipital region. The paths of the afferent nerve fibres in this locality have not yet been accurately worked out.

The affections of the nose and paranasal sinuses causing headache may be divided into

### I Non-inflammatory conditions

### II Inflammatory conditions

1 Cases of nasal headache due to non-inflammatory causes, where there is no suppurative inflammation of the accessory sinuses, are subdivided into

- (a) Pure pressure cases
- (b) So-called vacuum headache
- (c) Nasal ganglion neuroses

(a) In the pure pressure cases, due to terminal nerve pressure, we have hypertrophy of the middle turbinate bone, which impinges against the septum, which may or may not be deflected. Again in this group there may be adhesions between the inferior turbinate and septum, or between the inferior and middle turbinates and the septum, or the turbinate may be of practically normal size, but may be pressed upon by a markedly deflected septum. These pressures are responsible for a large number of headaches. This group may be subdivided again into

(a) Pain in individuals not constitutionally prone to headaches, and

(b) Pain in cases with the so-called neuro-pathic temperament. These latter patients have a low reserve of nervous endurance and readily succumb to slight continuous peripheral irritation.

### PURE PRESSURE CASES

Case 1 Almost constant left-sided supra-orbital headache since childhood. Marked deflection of nasal septum to left, pressing against middle turbinate. Submucous resection. Complete cure of headache.

Mrs. H., age 38, gives a history of an injury to the nose in childhood. She has had headache since childhood, growing worse in the last ten years. Pain is complained of almost constantly, and is felt above the left brow and in the left temple. The pain is dull with occasional severe exacerbations, when it becomes acute and is then accompanied by vomiting.

*Examination*—The nasal septum shows an acute angular deviation to the right, close to the floor of the nose. There is a corresponding sulcus on the left side with a slight deviation to the left, completely obliterating the view of the middle turbinate on that side. There is compensatory hypertrophy of the left inferior and of the right middle turbinate. Adrenalin applied to the left side of the nose gives temporary relief.

*Operation*—A submucous resection was performed, removing the deformed parts of the septum.

Six months later the patient reports that she has been absolutely free from headache since operation.

Case 2—Unilateral headache of fifteen years'

drowsy and forgetful, and slept most of the time

A radiograph, taken in the anteroposterior direction, shows a dark spot in the left sinus. This was thought to be due to diseased and thickened mucosa.

Examination of the nose showed that both middle turbinates had been removed, and the ethmoids and sphenoids of both sides opened. A radical operation, by the external route, was decided upon and performed under general anesthesia. The mucosa lining the frontal sinus was thickened, diseased and polypoidal. The same condition was present in the ethmoid cells, which were completely exenterated. The patient was immediately relieved of his pain.

*Resumé*—These cases represent fairly well the different types of headache due to lesions within the nose and sinuses. In the first three cases the headache was due to pressure. Mere septal turbinate contact is not sufficient to give rise to pain when the individuals are not constitutionally prone to headache. To cause pain there must be considerable pressure. As a rule the pain is fairly well localized over the affected side or sides. It is felt in the orbit, the nasal bridge, and often in the temple. It is always aggravated by any nasal irritation, and is often temporarily relieved by the application of adrenalin or cocaine to the affected region within the nose.

I have pointed out the difficulties in diagnosing vacuum frontal sinus headache, and have emphasized the diagnostic points in this condition, viz. a low grade frontal headache, worse in the morning, which is increased by reading, and which is accompanied by a tender spot at the upper and inner angle of the orbit (Ewing's sign).

Case 4 illustrates headaches caused by hyperplastic ethmoiditis and sphenoiditis, with a few physical signs in the nose, but diagnosed by the general nasal picture, the characteristic history and X-ray findings.

The other cases illustrate common types of

headache caused by acute and chronic sinusitis, of the suppurative variety.

It has been found that localization of pain in certain regions of the head is not typical for the affection of the different sinuses. For example, pain in the forehead may be caused by inflammation of the frontal, ethmoidal, maxillary, or even the sphenoidal sinus. On the other hand, the characteristic pain of sphenoidal disease is felt in the occiput or behind the bulb—as one writer has expressed it—or over the vertex. In maxillary sinusitis the usual point for the pain is over the anterior surface of the antrum, as well as in the teeth of the corresponding side of the upper jaw. Frontal sinusitis generally produces pain in the forehead, especially over the course of the supra-orbital nerve. In many cases of frontal sinus inflammation the pain is characterized by periodicity. At a certain time in the morning, usually ten or eleven o'clock, furious pains are felt over the affected sinus which persist for hours—perhaps until one, two, or even four o'clock in the afternoon—and then suddenly disappear. For the remainder of the afternoon and during the entire night the patient remains free from pain. On the following day the pain recurs at exactly the same hour.

#### CONCLUSIONS

1 Headaches are frequently caused by conditions existing in the nose or nasal sinuses.

2 These conditions may be either inflammatory or non-inflammatory, and in either case the headache may be relieved by proper treatment of the nose or sinuses.

3 Every case of persistent or recurrent headache warrants a careful physical examination of the nose with a nasal speculum, nasal probe, and transillumination of the sinuses, supplemented, if necessary, by exploratory puncture of the antrum, and radiography.

4 Headaches of nasal origin usually respond rapidly to removal of the causative pathologic condition.

nasal obstruction Several years ago began to have occipital and parietal headaches, right side For past three months headaches have been worse and are present constantly Eyes were examined at the Eye and Ear Infirmary four weeks ago and glasses given, without relief X-ray showed extensive deep frontals, not very clear Some thickening in ethmoids and antra, particularly on the right side Nasal septum was very thick and to the left, low down Sphenoid region well developed and only fairly clear

Operation under local anæsthesia Submucous resection of septum Exenteration of right ethmoids and sphenoid Frontal sinus opened intranasally Mucous membrane of the ethmoids was thickened and swollen and seemed to show beginning polypoidal changes Cure of headache

### B SUPPURATIVE SINUSITIS

*Case 5*—Pain over right supra-orbital region due to acute frontal sinusitis, following grip Simulates supra-orbital neuralgia Treatment, irrigation Relief of pain

Anna T, 21 years old, contracted influenza three weeks ago One week ago complained of pain over right supra-orbital region, which was severe and almost constant

*Examination*—The middle turbinate of the right side is large and puffy, and a discharge of yellowish pus is seen coming down between it and the external nasal wall Treatment—adrenalin and irrigations—completely relieved the pain in 24 hours

*Case 6*—Right supra-orbital headache, pain over right maxillary antrum and in teeth of upper jaw, together with right-sided exophthalmos caused by acute frontal and maxillary sinusitis following influenza Intranasal operation Relief

Mrs G H H, age 25 Eleven days ago had influenza with sore throat, fever, and pain in the limbs Five days later, dull pain developed over right maxillary antrum, which was present almost constantly The teeth of the right side of the upper jaw ached There was also tenderness of the right side of the roof of the mouth Two days later she experienced intense pain over the right eyebrow, temple, and ear The pain over the antrum of Highmore abated somewhat after a few days, but the frontal headache was severe enough to necessitate a dose of morphine

When first seen, the temperature registered 101.5°, by mouth

*Examination*—Slight swelling of the cheek over right maxillary antrum, and moderate right exophthalmos Nose narrow Low deflection of septum into right nostril with corresponding sulcus in left Right middle turbinate is somewhat hypertrophied, slightly polypoid, and adherent to septum anteriorly Pus between turbinate and external wall

*Operation*—The anterior portion of right middle turbinate was removed and the right

maxillary antrum pierced with a trochar Irrigation of antrum washed considerable pus Result the exophthalmos and antral pain disappeared in 24 hours The temperature became normal two days later, and the supra-orbital pain was completely gone five days after operation

*Case 7*—Headache and pain over left antrum and cheek of two months' duration caused by chronic maxillary sinusitis, left side First treated by intranasal puncture and washings Later by radical (Caldwell-Luc) operation Relief of headache and pain

Mrs R U, 45 years old, complained of pain in left antrum for six days, and soreness of one of the teeth of upper jaw Pus was seen coming down under the left middle turbinate bone Transillumination showed a dark antrum and ethmoids Punctured antrum under inferior turbinate and obtained about half an ounce of thick, foul-smelling, yellow pus This patient was treated at intervals over a period of two months with antral washings The pus failed to clear up entirely and she failed to obtain complete relief from pain An X-ray was then taken, which showed marked thickening of the ethmoid region and mucosa lining antrum Radical Caldwell-Luc operation was then performed on the antrum The mucous membrane lining the antrum was one-quarter of an inch thick and polypoidal in character and the cavity contained considerable pus After thorough curettage, a large counter opening was made into the nose through the inferior meatus and the wound in the canine fossa closed Cure of antral suppuration and relief of headache

*Case 8*—Adult male suffering with headache from chronic ethmoiditis and frontal sinusitis Operated intranasally in Europe without relief Cured by radical external frontal sinus and ethmoid operation

C J, a robust man of 39 years, came to the clinic with a history of bilateral mucopurulent nasal discharge and headache since childhood During the past three years he had had repeated intranasal operations for the cure of his nasal trouble in several of the large European cities His pain has always been over the frontal sinus, with one exception, when he had a bad attack of pain in the occipital region, relieved by intranasal opening of the sphenoid His last operation was performed eleven months ago in Hamburg Since then he has been free from pain over the right frontal, but his left-sided trouble has continued When first seen, a little over a year ago, he sought relief from periodic attacks of dull supra-orbital pain, left side These attacks usually lasted about two weeks Then there was a free discharge of muco-pus, followed by relief He was having one of these attacks when he came under observation, and stated that the supra-orbital pain began every morning about 9 A M and lasted until 3 P M He was very

## PROBLEMS OF TUBERCULOSIS

What would you like to know about tuberculosis or the methods employed in combatting it? No problem in medicine has received more careful and searching study than has been given to tuberculosis during the last generation, both by the medical profession alone and in conjunction with influential lay groups. Our information concerning the etiology of the disease, its development and prognosis are almost as complete as they can be made, but, nevertheless, a physician never comes upon a case of tuberculosis without encountering some perplexing symptom complex. It may have to do with early diagnosis, a patient may give a history of loss of weight and a cough, but bacilli cannot be found in the sputum, although specimens have repeatedly been examined. It may be a swollen joint where the patient gives a history that would suggest the possibility of congenital syphilis. It may be a chronic cough where it has been impossible to find rales. Possibly the physician must decide whether, in a particular case, he shall permit the patient with tuberculosis to attempt to bear a child. Certain cases give rise to particular problems concerning therapeutics.

It is a realization of the need for specific consideration of particular problems in connection

with tuberculosis that has prompted the Scientific Committee to prepare a program consisting of demonstrations and exhibits for Thursday, May 14th, as a part of the program of the annual meeting. The Committee's aim in preparing the program has been to collect material that would have a specific value to the physician in aiding him to solve problems similar to the ones suggested above. Neither accuracy nor thoroughness will be sacrificed for expediency in the demonstration, but each demonstrator will endeavor to make his contribution practicable for the practicing physician who does not consider himself a specialist in tuberculosis.

No physician in the State can afford to miss the annual meeting this year, and he should by all means come prepared to stay for the Thursday program. Those physicians living within a radius of one hundred miles of Syracuse, who may not be able to spare the time for the entire meeting, will easily find it possible to come back on Thursday.

The Committee hopes to complete its program in detail during the coming week and will publish it in the next issue of the Journal.

## SCIENTIFIC NURSING

Much advice is given to physicians that they should treat the patient as well as the disease. There are certain scientific essentials to be followed in the treatment of cases of sickness, and after the doctor has prescribed what he thinks the patient needs, he will give due consideration to what the patient wishes to have done. Some physicians whose services are widely sought, get a greater amount of fame from pleasing the patient than from their ability in scientific medicine, but every really successful physician has ability along both scientific and diplomatic lines.

We wonder if these two methods of approaching a patient are emphasized to nurses to the extent that they are to physicians?

We wonder if physicians give much thought to the human side of the nurse or her diplomacy, in her relation to the patient?

A nurse has a double relation to a patient. She is both a scientific advisor, and also a maid-in-waiting of a high class. A "practical" nurse is one who is strong in her maid-in-waiting duties and short in her scientific attainments.

Probably one of the greatest criticisms of a highly trained nurse is that her science excels her diplomacy and that she does not care to be a

maid-in-waiting. How many patients do we hear say about a hospital, "They get you well there, but they don't care about your feelings!"

There are conditions in which almost the only qualification that is required of a nurse is diplomacy—as, for example, the pre-operative care of a healthy person who is resting in bed for a few days waiting for an operation.

There are other conditions in which scientific attainments only are required of a nurse—as, for example, in an operating room, and during the post operative hours when the patient is either unconscious or too sick and weak to notice anything.

There are also conditions in which both scientific knowledge and diplomacy are required, as, for example, during the first week of convalescence after a major operation.

There are two ways in which a nurse can carry out a physician's orders. First, she may follow them literally and scientifically, and second, she may use some degree of diplomacy and independent judgment in adapting the physician's orders to the particular human being who is the patient. Suppose a hypodermic of morphine is to be given every four hours, catheterization is to be done at twelve o'clock, and the patient is to

## MEETINGS OF COUNTY MEDICAL SOCIETIES

The Medical Societies of the several counties are integral parts of the Medical Society of the State of New York, and their activities have an importance which equals that of the State Society. In fact the State Society reflects the activities of the local societies. If the County Societies are active, the members take a deep interest in the State Society.

The leaders of the State Medical Society feel that there is a mutual obligation upon the State and the County Societies that each shall support the other. The State Society is providing assistance to the County Societies along two lines,

first, publicity through the STATE JOURNAL OF MEDICINE, and second, the advice and assistance of the State Executive Officer.

We are gratified with the many evidences of progress in organized medicine in the several counties. We are receiving a greater number of reports on the meetings than ever before, and the reports show an increasing interest in civic medicine.

We suggest that our readers turn to page 630 and read the report of the meeting of the Livingston County Medical Society.

much of the unkind criticism of the trained nurse in the practice of her calling

During 1924, 5,246 pupil nurses attended nurse training schools approved by the Department of Education, an increase of nearly thirty-one per cent in ten years. The number of occupied hospital beds was 17,103, representing an increase of twenty-nine per cent in the same period. (Reports of Schools of Nursing, Univ of State of N Y 1925.) Pupil nurses are admitted to approved training schools on a preliminary education of one year of successful high school work or its equivalent, and yet of 767 pupil nurses who left the training schools in a single year for various reasons, 428, or fifty-six per cent, did so because of mental incompetency or instability. Annual pupil withdrawals of fifteen per cent from approved New York State training schools compare favorably with the general statement covering the entire United States that nearly one-half of the pupil nurses leave training before the course is completed. That girls with a better educational background are entering nurse training schools is shown by the statistics of the last four years, when about one-half the pupils had upwards of two years high school education on admission. A fragmentary survey indicates that from one-fifth to four-fifths of pupil nurses intend to pursue private duty nursing for at least one year after graduation. During 1924, 2,538 registered nurse certificates were issued by the Department of Education, an increase of about 100 per cent in a ten-year period.

After twenty-two years of existence of the registration law, of the 143 nurse-training schools approved by the Regents, only twenty-two complete the required standard training within the walls of the school. The State law only requires a minimum of two years of training. The course of two years is divided into four months of theory, eighteen months of practice, and two months of vacation, it is so proportioned that six months are devoted to surgical, five months to medical, three months to obstetrical, three months to pediatric, and one month to nutritional procedures. When put into hours the two years' course requires a total of about 6,520 hours, of which 6,000 hours are spent on practical, and 520 hours on theoretical work. The courses offered by the

143 training schools differ widely and vary greatly from standardized uniformity, a situation quite parallel to that which pertained in medical education prior to 1890.

It is as obvious that hospitals must have a nursing service as it is that they are instituted primarily for the care of the sick and conducted upon eleemosynary principles, on the other hand nurse-training schools now are educational institutions. Hospitals are maintained largely by gifts and endowments, and notwithstanding the economic return from hands and feet, it hardly is the province of the hospital to maintain from such funds educational institutions whose expenditures are mounting for salaries, laboratories, and maintenance.

For several weighty reasons, it would seem that the time has about arrived to place the responsibility for nurse education elsewhere than on the hospital. The State is conducting vocational schools in ever increasing variety. It certainly should have the management funds, and equipment properly to carry on nurse training as any other vocational education. The institution of a high school course<sup>1</sup> in nurse training to extend over a period of from five to six years, of which from one to two should be spent in practical bedside training in an approved hospital with proper adjustment of equivalents so as to permit students to be received from outside of New York State, would seem to offer a workable scheme whereby uniformity of subjects taught and of teachers' qualifications readily could be secured. Hospital funds, equipment, and responsibility would be greatly relieved, a greater number of highly trained nurses would be available, the student turnover in the hospital would be practically nil, and the graduation of the nurse take place at a proper age, and after a course of training uninterrupted from age or educational disqualifications. In New York State more than seven hundred institutions with upwards of 40,000 beds care for the sick and the convalescent. They are widely scattered throughout the State and require nursing service of all degrees. They would furnish abundant clinical material available for early as well as late teaching and experience.

A T L

<sup>1</sup> Nurse Training as an Educational Project.—A. T. Lytle  
New York State Journal of Medicine March 14 1924

## BILLS SIGNED BY GOVERNOR SMITH

### LAW OF 1925

227	S 671	Cole	Physically handicapped persons	367	A 1321	Lattin	Health Law, vital statistics
275	S 681	Cole	Dead bodies may be incinerated	368	A 536	Lattin	Health law, vaccine
365	A 1539	Lattin	Health law, pharmacy	369	A 1027	Lattin	Health law, cadavers

be kept quiet. If the patient is restless and in pain at 11:30, shall the nurse give the hypodermic and do the catheterization at that hour, or wait a half-hour longer? If she deviates one iota from literal orders, what will the physician say to her?

To what degree is the hospital physician responsible for the cast-iron, hard-boiled attitude of some nurses which leads them to carry out orders to the letter?

But some nurses who are skilled scientifically lack plain, ordinary tact. Suppose such a nurse adjusts the pillows and the patient still finds them uncomfortable, shall the nurse insist that they *are* comfortable, for does she not know how to adjust pillows and to make beds? Let any male physician answer this question: "Can you put a hat on any man's head to his satisfaction, or wipe his face?" He will invariably wish to change the position of his hat and to give his face another dab with the towel. A nurse *must* use diplomacy as well as scientific judgment. In fact, the two are one.

Why are the nurses who have great scientific skill found in large hospitals more often than in private practice? We have a suspicion that one reason is that their science exceeds their diplomacy. The hospital doctor is likely to be entirely satisfied if his orders are carried out. If his patient is in a hospital, he judges the nurse by the record sheet which she keeps, and he

gives little heed to her diplomacy, but if the patient is in a private home, he is compelled to hear about the courtesy, patience, and diplomacy of the nurse.

The excellent custom of excluding friends from the sick room of a hospital has its objectionable feature in that it deprives the physician of the principal means of judging whether or not the nurse is pleasing the patient.

It may be excusable for a nurse to refuse to notice the whims of a ward patient where other patients also need attention, but how about a private case who has a special nurse by day and another for the night at six dollars each? It would seem that at that price both scientific efficiency and diplomacy could be secured in full measure.

A physician who fails in courtesy and tact gets a quick call-down, or it may be that the patients and their friends will tolerate him during the few minutes of his visit. But a patient is with the nurse hour after hour, and depends on her for peace of mind and contentment.

Physicians give all manner of advice to their assistants and deliver post-graduate lectures on tactful ways of pleasing patients. Would it not be well to give some post-graduate talks to nurses on how to be diplomatic and tactful with their patients?

F O

## NURSE EDUCATION

There are people, especially physicians, who still consider nursing a trade and not a profession, they consider the quality and desirability of the nurse's service to be determined by the character of the hospital in which her training occurred. The law registering nurses, placed on the statute books of New York State in 1903, established a minimum standard for schools of nursing, and by placing its administration under that of other professional schools of the Department of Education gave to nurse training the status of a profession. The characteristics of nurse training which classify it as a profession, as one educator puts it, are a great amount of individual responsibility, the derivation of its materials from science and scholarship, the possession of a definite technique which may be communicated by educational means, and a service rendered primarily with a view to public service and not to profit.

The first law protected only the title of Registered Nurse (R N), as only graduates of schools registered by the Regents could take the licensing examination. As the public did not differentiate the titles Graduate, Certified, or Trained nurse from that of Registered nurse, the law did not protect it from graduates

of quack nurse-training schools, so in 1920 the law was so amended as to make it illegal to use the title trained, graduate, certified, or registered nurse unless the user was a graduate of a school approved by the State Department of Education and was licensed by the Board of Regents to practice as a Registered Nurse. No hospital is compelled by this law to have its training school approved by the Department of Education, such approval rests exclusively with the hospital. As the law could not be made retroactive, and as hundreds of nurses had graduated from approved hospitals or had been actively engaged in nursing for many years, before the law became effective, all such nurses as so desired were permitted on application to be licensed to use the just mentioned titles. On November 1, 1924, 18,879 individuals were listed by the Department of Education as Registered Nurses and permitted by law to use any of the other titles. A very large number of these Registered Nurses never have attended any hospital training school, a number are graduates of correspondence schools, the sheep are still herded with the goats. To the necessity for this unfortunate situation must be ascribed

# State Department of Health

## SUDDEN DEATHS AFTER DIPHTHERIA

The Department recently received a report from a district state health officer of the circumstances in regard to the sudden death of a boy who had diphtheria six weeks previously. This child, two years of age, had apparently recovered, but was left with some paralysis. While he was attempting to climb on a piano, he dropped dead.

Such fatalities are not at all infrequent. The Division of Communicable Diseases has reviewed the special diphtheria death reports submitted since January 1, 1924, and has found sixteen other cases of sudden deaths from cardiac involvement following diphtheria. Five of these occurred more than three weeks after the onset of the disease. In seven cases the reports indicate that the patients were not kept in bed and that this was an immediate factor in the cause of death.

The longest time between onset and death was forty-four days. This interval was given for two adults, aged 38 and 64. The ages in the entire list ranged from 17 months to 64 years.

Two patients left their beds merely for toilet purposes and immediately afterwards collapsed and died. In another case it was stated that "the patient was nearly well, got out of bed and died before the doctor could get there." In another, "death occurred after the child had been playing with another child tossing a ball."

In nine other cases in which there was no statement as to whether or not the deaths were sudden, it was reported that the patients were allowed to sit up or get out of bed, often against the physician's instructions.

According to Holt and Howland (*Disease of Infancy and Childhood*, Eighth Edition, p. 1008), "patients should invariably be kept in bed for at least a week after the throat has cleared, and much longer if any tendency to

cardiac weakness is seen. The pulse should be carefully watched, and irregularity, intermission, diastolic, or a weak first sound of the heart, should make one apprehensive. An abnormally slow pulse is generally more serious than one which is rapid. In such circumstances the patient should be kept recumbent and absolutely quiet, since fatal syncope may be the result of a violation of these rules." Ker (*Infectious Diseases*, Second Edition, p. 446), states that "it is of the utmost importance that, from the moment diphtheria is definitely diagnosed, the patient be rightly kept in the *recumbent posture*. Sitting up should not be allowed on any pretext whatever, and even the slightest exertion, such as reaching to a bedside table, should be strictly forbidden.

If the attack is a very slight one, the patient may be gradually propped up in bed from the middle of the third week, and, if no harm results, allowed to get up for an hour or two early in the fourth. In really severe cases, however, it is safer to keep him in bed for at least six weeks, the tendency for the later forms of paralysis to appear about the sixth week making such a precaution advisable. Adults should not resume work or children return to school for some weeks later, and a complete change of air is often of great advantage."

It is evident that greater care is needed in this matter. Not only should physicians keep careful watch of the pulse and heart, but also every possible effort should be made to impress on parents the likelihood of the serious consequences which may follow even slight exertions by the patient. This is, of course, especially necessary if antitoxin has been given later than the first day of the disease, or if there is any indication that an insufficient amount was given on the first day.

## SUPPOSED TYPHUS FEVER PROVES TO BE DRUG RASH

The Department recently received a report of a case of typhus fever in a small village. Upon investigation it was found that on or about February 20 this patient had developed symptoms of gripe with quite severe frontal headache. The patient had purchased a package of headache tablets and doubled the advised dose, taking the contents of the entire package within a few hours "in order to hurry his recovery." Not content with this, he also took several headache tablets of another variety "as a matter of precaution."

It is hardly surprising that after this vigorous attempt at self-medication the man developed a soft thready pulse, cyanosis of the lips and a scattered rash which made its appearance a day or so after the ingestion of these drugs, but which subsided within a couple of days without leaving any discoloration.

Following the later developments of the case, the attending physician was quite willing to change the original diagnosis.

# LEGAL

By GEORGE W. WHITESIDE, Esq.  
Counsel Medical Society of the State of New York

## CLAIMED BREACH OF CONTRACT TO CURE

In this matter the plaintiff, suffering from a genito-urinary condition charged that the defendant physician was guilty of fraud and deceit and sought to recover the amount which he had paid to the defendant for attention and treatment. He further claimed that the defendant physician agreed to treat him for the condition, until such time as he was cured, for the amount which he had paid.

The patient had made three visits to the physician, at which visits extensive diagnostic examinations were made and laboratory analyses were had of the urine specimens, the laboratory charges being paid by the defendant. After the three diagnostic visits the physician gave the plaintiff electrical treatment, charging him a stated price for the same and advising the plaintiff that the succeeding visits would be at the same price.

The defendant was a specialist in genito-urinary conditions and upon the plaintiff's call advised the plaintiff that he would undertake, for \$50 00, to make a complete and exhaustive diagnosis of the plaintiff's condition, that the diag-

nosis would consist of three visits—on the first visit a thorough physical examination and specimens of pus for microscopic analysis—on the second further physical examination and the taking of a seven-glass urine test for laboratory analysis—and on the third visit an internal examination of the urinary canal by means of a telescopic instrument—and that from these examinations and the laboratory reports on the pus and urine the best treatment for the plaintiff's condition would be determined by the defendant, the plaintiff to be charged a reasonable fee for such treatments.

At the time of trial the plaintiff abandoned the complaint of fraud and deceit and charged that the defendant undertook to treat him until cured for \$50 00 and testified to this effect. The defendant offered his testimony in proof of the arrangement that the payment of \$50 00 was to cover the three diagnostic visits and laboratory analyses. The jury, however, determined the issue in favor of the plaintiff and the judgment was affirmed by the appellate court.

## DEATH—ETHER ANAESTHESIA AT DELIVERY

An action was brought to recover for the death of the plaintiff's decedent, it being charged that the defendant, as a physician, was employed to attend the decedent at child birth, and that because of his carelessness and negligence in the administration of the anaesthesia, the decedent died of ether poisoning.

The defendant, a general practitioner, was called to attend the decedent at which time she was in labor and being attended by a midwife. She was about thirty-eight years of age. Upon examination the defendant found that she was about to be delivered of a full-term dead foetus, her labor being difficult and painful. The defendant sterilized his instruments and gloves and prepared the parts of the patient, and also prepared with sterile towels a table upon which the patient was placed. After preparation of the patient and himself the physician handed the can of ether to the midwife, directing her to let fall one drop at a time on a gauze mask which had been prepared for the purpose of administering the anaesthesia. The physician watched the midwife let the ether drop steadily

for about five minutes, at which time the patient was fully anaesthetized. He then inserted his forceps in the vagina, getting hold of the head of the foetus. At this moment the physician noticed that the patient had become cyanosed. He immediately withdrew the forceps, suspended the application of the ether and resorted to massage and artificial respiration. He also administered two hypodermic injections of caffeine and sodium benzoate. The heart action gradually grew weaker and the breathing ceased. An injection of strychnine-nitrate was also administered. The patient did not revive and died in about fifteen minutes after the first application of ether. The cause of death was stated as shock from ether anaesthesia while doing a high-forceps delivery of a full-term dead foetus, and the contributory cause status lymphaticus, no autopsy being performed.

The plaintiff failed to prosecute the action. A motion was made to dismiss the same for lack of prosecution which motion was granted, favorably terminating the action in favor of the doctor.

The New York Academy of Medicine is composed of physicians of professional standing in general practice, the specialties, and public health. It has taken a leading part in the broader aspects of civic affairs, and its reports carry weight and influence. Nearly all its members also belong to the County Medical Society.

*The County Medical Society*—The Medical Society of the County of New York has 3,334 members, or about 61 per cent of the physicians of the County. This proportion is about the same as that for all of Greater New York. The Kings County Medical Society enrolls about 60 per cent of the physicians of the County, while 72 per cent of the physicians outside of Greater New York are members of County medical societies. Still, the number of physicians in New York County is so great that nearly one-third of the members of the Medical Society of the State of New York live in New York County.

The New York County Medical Society holds eight meetings a year, or one each month except during the summer. The Society holds its meetings in the building of the Academy of Medicine at 17 West 43rd Street, and maintains its offices there.

*Committee Activities*—The great number of members of the New York County Medical Society precludes the possibility of conducting the affairs of the Society by discussions in open meetings. The activities of the Society are, therefore, carried on principally by committees, just as they are in other County societies—for it is only a few members in any County society who have the time, the inclination, and the qualifications to devote to medical civics. The internal affairs of the Society are administered by the Comitia Minora, and its external activities are directed principally by the Committee on Civic Policy which has been organized in recent years to coordinate the activities of the Society, and which reports on these activities to the Comitia Minora for action. This Committee is composed of eight members in addition to its chairman, Dr. Frederick E. Sondern, and has under its direction several special committees on each of which one of its members acts. These special committees are those on Hospitals and Dispensaries, on Nursing, on Roentgenological Laboratories, on Clinical and Pathological Laboratories and on Press and Publicity. They do an enormous amount of detailed work, much of which is not made public, but the reports are made to the Committee on Civic Policy and to the Comitia Minora. The important nature of the work that is done quietly and efficiently by these committees is indicated by a few examples.

The Committee on Roentgenological Laboratories has done an enormous amount of work in the investigation and control of inept X-ray operators in beauty parlors and the offices of chiropractors.

The Committee on Pathological Laboratories

has undertaken the control of commercial laboratories in which unqualified persons pretend to make expert examinations of blood, urine, and other specimens on whose results health and life may depend.

The Committee on Press and Publicity is endeavoring to stop the broadcasting of alleged health talks by charlatans.

The Legal Department of the Society has followed up complaints against illegal practitioners, and has assisted in driving many out of business by working with the Department of Health and District Attorney's office.

The amount of work handled by the committees and Comitia Minora each year is enormous, the Comitia Minora often sitting until midnight. If it were proper to disclose the details of the work of the Society, the Secretary, Dr. Daniel S. Dougherty, could tell interesting stories of the detection and prosecution of illegal practitioners, and of measures for uplifting the standards of ethics and medical practice.

The correspondence and details of the Secretary and Treasurer's office are of such importance that they require two full-time secretaries and several part-time clerks.

The Milk Commission conducts one of the most important of the routine activities of the Society, that relating to certified milk. The Commission consists of twelve leading pediatricians and laboratory workers who have charge of the inspection and control of dairies and the certification of their milk. The details of the work are done in the laboratory of the Department of Health under the direction of Dr. W. H. Park, but the funds for the work are provided by the dairymen. The Commission renders real service of advice and certification to the milk producers, for which they are willing to pay a fee, which makes the work entirely self-supporting.

The Committee on Legislation has been extremely active not only during the sessions of the Legislature, but throughout the year, with the result that the New York County Legislators have supported the Medical Practice bill and other legislation raising the standards of professional work.

A special committee on Periodic Health Examination was appointed during the past year and its work is a real contribution to the movement. One feature of its activity has been a symposium of sixteen lectures by experts in the various specialties, each in his own line, setting forth the salient features for which an examiner should look when he examines a patient. The lectures tell an examiner how to make an examination, so far as any verbal or written instruction can do so. Abstracts of many of the lectures have been published in this Journal.

*The Medical Week*—The Medical Society of New York County supports its own publication called the *New York Medical Week*. Each issue

# MEDICAL SURVEY

## MEDICAL SURVEY, NUMBER 8—NEW YORK COUNTY

**EDITOR'S NOTE** The information on which this Survey is based was obtained with the co-operation of Dr Samuel J Kopetzky, President of the Medical Society of the County of New York, Dr Daniel S Dougherty, Secretary of the Society, and Dr Frederic E Sondern, Chairman of the Committee on Civic Policy, and by Dr Linsly R Williams, Director of the New York Academy of Medicine

*Medical Circles of Influence*—New York City is divided into five counties whose boundaries are the same as those of the Boroughs of the City. Each county has its own County Medical Society, and the physicians have their own medical affiliations. The counties have many of the characteristics of separate cities.

The reasons for the medical individuality of the several counties of Greater New York are historic, geographic, and economic. The huge unwieldy size of the city also promotes the individuality of its component parts.

While New York County formerly constituted the entire City of New York, it now comprises only one-third of the population of the city and one-fifteenth of its area. Yet the county is a great medical center for not only purely medical organizations, but also for lay organizations whose activities are allied to those of medicine. It is but natural that the County should contain physicians whose eminence and influence are comparable to those of its great financiers and lawyers. There are also a very great number of physicians whose practice is confined to a limited class and section, such, for example, as the Italians in their quarter of the city, or the negroes in their locality.

It is characteristic of a great city that its people tend to form rather limited circles of affiliation which often seem narrow to outsiders who have not experienced the hugeness of every phase of life in the city. A physician in New York County is compelled to associate with a restricted circle of confreres which, nevertheless, may be larger than the entire body of the medical profession in most other cities. New York physicians of eminence often deplore the physical impossibility of their forming wide medical associations with general practitioners, and when they attend a meeting of a rural county society, they express their jealousy of their country brethren, all of whom call one another by their first names. It is not intention, but force of circumstances that compels the physicians of New York to group themselves into rather restricted circles.

New York County is the center of medical organizations, both professional and lay, whose activities are nation wide, and which do active work in the city also. The hospitals of New York County, the department of Health, the Tuberculosis Association, and other organizations operate on such a vast scale and have so many ramifications that a complete medical survey of the County would be well nigh impossible. We will, therefore, confine our description of medicine in New York County to an outline description of its two representative organizations—the County Medical Society, and the New York Academy of Medicine. These two societies are organized and conducted along the same lines as those of similar organizations in other parts of New York State.

*Number of Physicians*—New York County has an area of about 22 square miles. Its population is 2,400,000, as estimated by the Department of Health of Greater New York.

New York County has 5,556 physicians, according to the medical directory of the Medical Society of the State of New York. This gives a proportion of one physician to every 432 of population. The proportion in Kings County is one doctor to every 835 of population, in Bronx County, one in 1,220, and in Richmond County, one to 1,300. The proportion in New York State, outside of Greater New York, is one doctor to 770 of population.

Since the average number of persons per physician in New York County is 432, or only one-half or one-third the proportion in other parts of New York State, one wonders whether or not the physicians of the County are as prosperous as those elsewhere. The financial rewards to some physicians are very great, especially to specialists to whom cases are referred from far and near. It is doubtful that the average income of the New York County doctor is greater than that of his rural confrere. The average four hundred and thirty-two of population of New York City has no more money and pays no more to a doctor than the same number of persons up-State.

*Medical Organizations*—The Medical Society of the County of New York represents the profession of the County, and a membership in it is open to every ethical practitioner in the County. It is an integral part of the Medical Society of the State of New York, and the benefits that it confers upon its members are the same as those that accrue to the members of other county medical societies.

# NEWS NOTES

## ENDOCRINOLOGY IN PERIODIC HEALTH EXAMINATIONS

By WALTER TIMME, M.D., New York

Abstract of the twelfth lecture in the symposium on Periodic Health Examinations conducted by the Medical Society of the County of New York given January 22, 1925

THE topic of my lecture is the internal glandular system in its relation to constitutional development

About sixty per cent of the cases in which there is either an excess or a deficiency in the functions of the pituitary and other glands of internal secretion may be traced back to very early periods of life, and even to one's ancestors. The abnormalities may not recur in the type in which they originally appeared, but in tables of inheritance the various types may succeed one another without any definite order, and subject to many metamorphoses.

About sixty per cent of cases of endocrine excess or deficiency belong to one type called the *Status hypoplasticus*. In this constitutional type the cardio-vascular system is undersized and inadequate, as are also the pituitary, thyroid and adrenal glands. On the other hand, some glands are enlarged, especially those containing lymphoid tissue, such as the thymus, lymph nodes, spleen, and liver. The blood of a person who has a hypoplastic type of body will show a low polymorphonuclear count, low coagulation curve, low blood sugar, and a low alkaline reserve.

Persons of the hypoplastic type will not show a high poly blood count when infection occurs. A surgeon is likely to go wrong if he depends on a high polymorphonuclear count as an indication for operating on one of these cases.

Patients of this type have a low blood sugar content—70 or 75 mg per 100cc. Since muscular activity depends on the percentage of blood sugar that reaches the muscles, these patients have a great tendency to fatigue.

The long coagulation time of the blood—10 to 20 minutes,—leads to bleeding and purpura. A very slight bruise will cause purpura in the skin of these persons. The tendency to bleed may lead to secondary hemorrhages of important organs such as the brain after slight injuries, or even after moderate hyperemia.

The low alkaline reserve of the blood leads to periodic symptoms of acidosis.

Patients with the hypoplastic state have extremely loose joints. This looseness is exceedingly troublesome when it affects points which are normally snug and tight, such as the sacro-iliac. Loose sacro-iliac points produce low back-ache for which the only relief is a tight band

which will hold the joint firmly in place, as a substitute for the ligament.

Looseness of the joints of the foot leads to flat foot and its accompanying pain and disability.

What becomes of these patients? Many die young of sudden fright, or of slight infection, or of a mild narcosis such as a few whiffs of chloroform. The cause of death is likely to be unknown, for their physicians have not realized that there was anything seriously wrong with their constitutions. The practical application to periodic health examinations is obvious.

If these patients survive to adult life, what has happened to allow of this? There is a balance among the glands by which one may overcome the deficiency of another. If, for example, the pituitary enlarges the patient has an increase of blood sugar, if the thyroid enlarges, he has a more rapid assemblage of sugar and a shorter coagulation curve. Thus is what happens to the cases which reach an approximately normal adult state, but the compensation is often only partial, and these persons remain handicapped for life.

Compensation may be sufficient until an extra strain is put on the body. An example is the influence of puberty on a boy in whom the pituitary, while previously somewhat inadequate, becomes markedly so when puberty demands an extra supply of the secretion of the gland. Relative hypopituitarism results and the boy then becomes lethargic and fat.

By examining a case early in life by an ordinary physical examination, the hypoplastic state may be readily detected and remedied.

On the other hand, suppose the thyroid has been called on for over-activity during childhood. When puberty calls for added activity, the gland cannot respond and there develops the symptoms of relative hypo-thyroidism—with enlargement of the neck, called goitre, sluggishness, increase in weight, mental retardation, dryness of the skin,—all of which go with low oxidation. If the early signs of this condition had been recognized and corrected in infancy, there would have been no hypo-thyroidism later on.

The symptoms of hypo-adrenalism are vague, excepting those of inordinate fatigue and low blood pressure, but these symptoms also accompany disturbances of the thyroid and pituitary.

contains about sixteen pages of editorial comments, news notes and announcements. The periodical is almost a necessity in informing the great number of members of the County Society regarding its activities and in maintaining their interest in the organization. It is a live, high class medical publication and a model which other County medical societies could follow with profit. Its success has been due largely to Dr. Samuel J. Kopetzky, who is now President of the County Society.

The activities of the Medical Society of the County of New York have not been spectacular in any sense, but have consisted in the quiet performance of numberless details of civic duties which have the same relation to the medical profession and the public that the high class practice of medicine has to an individual patient.

*The New York Academy of Medicine*—If the activities of the County Medical Society may be compared with those of a physician in general practice, those of the Academy of Medicine are like the work of a medical consultant. The work of the County Society is intimate and personal, the work of the Academy is impersonal and scientific.

*Property and Endowments*—The New York Academy of Medicine now has 1,750 members or "Fellows," and 75 Associate Fellows. It was founded in 1847 for the purpose of promoting the science and art of medicine, the maintenance of a medical library, and the promotion of public health. It has consistently carried out these purposes to such a degree that its Fellows and their friends have endowed it with approximately nine hundred thousand dollars. The income of a fund of a million and a quarter dollars has been allotted to the Academy by the Rockefeller Foundation for the extension of its library and educational activities, and the entire principal will be turned over to the endowment fund when the Academy has inaugurated its new activities satisfactorily. The funds at its disposal enable it to carry on scientific work unhindered by adverse opinions of various medical groups.

The Academy has title to its own building at 17 West 43rd Street, which has five meeting rooms, houses the library, and provides offices for the Medical Society of the County of New York and the Medical Society of the State of New York. It is expected that in 1927 the Academy will occupy a new building at 103rd Street and Fifth Avenue, provided by the gift of a half million dollars by the Carnegie Corporation.

*Promotion of Medical Science and Art*—The first of the objects of the Academy, that of promoting the science and art of medicine is carried on by means of scientific meetings and a Bureau of Clinical Information.

Two scientific meetings are held monthly for the presentation of scientific papers and discussion of them by the Fellows. With the growth of medicine and the increase in the number of specialties twelve sections have been formed, each with a membership of from one hundred to three hundred and fifty. Each section meets monthly. All meetings of the Academy and its sections are open to the medical profession generally and to medical students.

The Academy Committee on Medical Education conducts a Bureau of Clinical Information which prepares daily lists of operations and clinics, and meetings in Greater New York. It posts the lists on the bulletin board of the Academy, and mails them to numbers of physicians outside of the city. The Committee also collates information regarding the post-graduate courses of instruction that are available. It is recognized as the authoritative source of information regarding what courses of instruction are available to a physician seeking clinical knowledge.

*The Bulletin*—The Academy has begun the publication of a thirty-six page bulletin which is designed to carry news of its activities, and some original scientific articles. The publication takes the place of the transactions which were published from 1860 to 1901. The first number was issued late in March, and will be followed by monthly issues.

*The Library*—The Academy maintains a public medical library of 140,000 volumes. This library is the second in size in the United States, and is exceeded in size by only the Library of the Surgeon General in Washington. It is open to physicians generally at certain hours.

The quarters of the Library are crowded, and the space does not permit of efficient service by the librarians. It is proposed to give the readers modern library service and assistance when the new quarters are occupied.

*Public Health*—The Academy has always taken a deep interest in the promotion of the larger phases of public health. Its committees have studied the needs of hospitals and dispensaries, and it has recently published a book on the hospital situation in the city.

An intensive study of child health has been made, and will be published during the year.

Studies have been made regarding the adequate care of chronic patients, and the need of better treatment in convalescent homes.

The training of nurses and nurse anesthetists has also been considered.

This is only a partial list of the lines of work undertaken by the Academy. It is proposed to amplify the scope of the activities when the funds become available and the work is organized.

by the Society and favorable action requested by the Board of Supervisors, and

WHEREAS The Livingston County Board of Supervisors completely ignored the wishes of the Physicians of the County as represented by the Livingston County Medical Society by designating a Laboratory that is inconvenient and had not met the requirements of the State Department of Health,

Therefore, be it Resolved, That the Livingston County Medical Society in regular meeting at Geneseo on March 24th puts itself on record as being opposed to the action taken by the Board

of Supervisors in regard to the County Laboratory contract, as let, wherein they completely ignored the request of the Society

Dr C Fiero, Chairman Committee on revision of the County Fee Bill, reported progress in making suitable revisions and promised to furnish the Secretary with a complete revision so that copies might be sent to all members prior to the next meeting, at which time any corrections could be made and its adoption assured

The Society adjourned at 11 45 P M after one of the most interesting and instructive meetings held within recent years

L A DAMON, *Secretary*

## BULLETIN OF THE NEW YORK ACADEMY OF MEDICINE

The New York Academy of Medicine has resumed the publication of its *Bulletin* after it had been suspended for twenty-four years The *Bulletin* was first issued in 1860, and was continued up to 1901, either as separate pamphlets or as transactions It is now called the second series, and Volume One, Number One, and a copy has just reached us

The new *Bulletin* has thirty-six pages, each about half the size of a page of this JOURNAL It contains a history of the former series, and a financial report of the Academy It prints the inaugural address of the President, Dr Samuel

A. Brown, which recites the story of the home of the Academy It carries a description of the collection of the first editions of the poems of Dr O W Holmes, and of artistic portraits of distinguished physicians, both of which collections have been presented to the Academy by Dr Charles L Dana Ten pages are devoted to two scientific articles on pneumonia Announcements of meetings and lists of committees are published

The *Bulletin* is a part of the educational system of the Academy, and is well designed to inform the reader about the activities of the organization

F O

## EXHIBIT OF ANATOMICAL BOOKS

Physicians who have a liking for medical history and art will be interested in an exhibition of early anatomical books in the Grolier Club, 47 East 60th Street, New York City Here are shown many works which have a high artistic as well as scientific value The reason seems to be that in the time of Vesalius the painters who went to the chemists to buy their pigments met the

physicians who came to buy pills and potions, and the two dissected bodies together—the painters for art and the physicians for science. It was only natural that the painters should give even the skeletons a lifelike pose, and should depict every part of the body in action

The exhibit is open every day from 10 o'clock until 6, and admission is free

F O

When the pituitary begins to compensate, its increasing size causes it to press upon the sides of the bony cage in which it lies, and headaches develop. The headaches come on periodically, after exertion or fatigue, and after acts of mental concentration. The headaches may continue for many years until the pressure causes a sufficient enlargement of the pituitary fossa, when the pain ceases. The fossa may be seen by

means of X-ray pictures, and in a series in such cases it may be seen to enlarge. Some of these cases have eye troubles owing to the location of the pituitary beside the optic and oculo motor nerves, and so the headaches are sometimes thought to arise from the eyes.

The conditions that have been described are only a few of the more common ones which are attributable to the early status hypoplasticus.

### LIVINGSTON COUNTY MEDICAL SOCIETY

A regular meeting of the Livingston County Medical Society was held at the Big Tree Inn, Geneseo, at 6 P. M., March 24, 1925. The President, Dr. H. A. Patterson, presided, and there were 18 members and 12 guests present.

Dr. D. C. Wilson of Clifton Springs gave a paper on "Carcinoma with Spinal Metastasis." He reported 21 cases of spinal carcinoma secondary to malignancy in various other parts of the body. A lantern slide X-ray of each case was shown demonstrating the lesion present. The paper aroused considerable discussion among the members concerning differential diagnosis between this condition and Pott's disease and other affections of the back.

Dr. F. H. Richardson of Brooklyn gave a talk on "Infant Feeding," and made an eloquent plea for breast feeding. His statistics showed that it was possible for 97 per cent of all mothers to nurse their children if given the proper instruction and encouragement by the family physician. He described methods of milking the breasts in order to stimulate further production, and gave various methods of complementary feeding while the breasts were being stimulated. A general discussion followed the paper.

Dr. A. Pfeiffer, Head of the Division of Venereal Diseases of the State Department of Health, next demonstrated a collection of wax models showing the various skin manifestations of syphilis.

Dr. B. R. Wakeman, District State Health Officer, addressed the Society on the subject of Children's Health Clinics. His proposal that this work be taken over by the Society and that at the clinics in the various towns of the county, the members themselves act as examiners, did not meet with approval. The general feeling, as brought out by the discussion, was against such clinics and no action in regard to the matter was taken.

A motion requesting the State Department of Health to assist in instructing the Public Health Nurses throughout the county regarding infant feeding methods as previously outlined by Dr. Richardson, made by Dr. Driesbach and seconded by Dr. Burt, was passed.

The Secretary read a letter from Genesee County Society inviting the members to join in a Tri-County meeting to be held in Batavia in

April. A vote showed a majority in favor of accepting the invitation.

The Society voted to accept an invitation from Dr. Shanahan to hold its next meeting at the Craig Colony on the first Tuesday in May.

Dr. Wakeman extended to all members a cordial invitation to attend the next meeting of the Steuben County Society, which will be held in Hornell on May 18th, and promised to send a program to each member in advance of the meeting.

The following physicians were elected to membership: Drs. Glendolyn Cowper Schwing, Nunda, Harold E. Schwing, Nunda, Paul Levi, Sonyea.

A resolution relative to the death of Dr. Barton F. Andrews was submitted by the Committee, Dr. F. J. Bowen, and Harold A. Patterson, and was adopted.

Dr. W. E. Lauderdale, Chairman of the Laboratory Committee, gave a report of the activities of the Committee. Every effort had been made to secure the adopting of the Craig Colony Laboratory, but the Board of Supervisors had ignored the requests and had made a contract with the Laboratory of the Jackson Hotel and Health Resort. There was much discussion of the subject and the consensus of opinion was that the Society had been treated unfairly and that its disapproval of the actions of the Board of Supervisors should be properly registered. Dr. W. E. Lauderdale and the Secretary were appointed to draft such a resolution, a copy of which was to be sent to the Board of Supervisors, to the State Department of Health, and if possible published in all the County newspapers. The following resolution was submitted:

WHEREAS The Livingston County Medical Society respectfully petitioned the Livingston County Board of Supervisors to establish a County Laboratory that would meet with the State Department of Health requirements and would thereby secure the customary \$1,200.00 aside from the State as provided for in Chapter 638, Laws of 1923, of the State of New York, and

WHEREAS The Laboratory of the Craig Colony being available for this purpose and meeting all the requirements of the State, was approved

# THE DAILY PRESS

We have received an unusually large number of medical clippings during the past week—a great many of them record health lectures and exhibits. Health talks always make readable news, even if the hearers cannot remember all the points that are made.

A considerable number of clippings relate to health centers and their activities especially in tuberculosis and child welfare. Schuck testing and the administration of toxin-antitoxin are described in several papers.

Vaccination talks and clinics are frequently described, and every newspaper commends the procedure. While one or two New York papers condemn vaccination, our clippings show that the up-State papers support it.

A crusade against spitting in public places is noted in the *Syracuse Post-Standard*, March 25th. We have commented on the need of emphasizing the infectious nature of the excretions of the nose and throat. The *Syracuse* lectures are along the right lines.

The *Saratoga Saratogian*, March 23d, contains half a column account of the movement to vaccinate the school children of the city. The account says that parents are requested not to come with the children who are to be vaccinated for both doctors and nurses will be present at the centers where the vaccination will be done.

The account quotes the Health Officer, Dr. Moriarta, as follows:

"At present we have no cases of smallpox in Saratoga Springs. However, from surrounding cities and villages come reports of many cases from which persons carrying this disease may come to our city and live in our midst, thus becoming an active menace to ourselves and the children of this city. Skidmore College has thought it of sufficient importance to enforce vaccination of all students.

"To decline vaccination is to place personal inclination above public good and is against every principle of citizenship. Smallpox can be prevented by vaccination and by vaccination only."

The *Buffalo Express*, March 25th, contains the following account of a Children's Health Demonstration in Buffalo:

"A children's health demonstration, to cover a period of five years in the section of the city where the greatest infant mortality exists, has been begun under the general auspices of the Buffalo Council of Social Agencies. The area to be served comprises the baby clinic at No. 404 Seneca Street and a new baby clinic at No. 378 Elk Street, in general covering the first sec-

ond and third wards of the city. Physicians and district nurses are in charge.

"Other agencies co-operating in this effort to bring about a reduction in infant mortality are the Buffalo City Hospital, Junior League, Buffalo Home Bureau, Charity Organization Society, Erie County Board of Child Welfare, International Institute Buffalo Foundation, Bureau of Public Welfare, Department of Charities and Corrections of Erie County, members of the medical profession, members of the clergy and the public schools. It is hoped not only to reduce infant mortality, but also to improve health conditions generally in this section of Buffalo. The Buffalo City Hospital will maintain morbidity and mortality records for all patients treated at central or branch dispensaries, in the home or in private hospitals at public expense.

"Cases of sickness other than accident, first aid or trivial ailments are not to be treated at these demonstration clinics, but are to be referred to the proper clinics or to private practitioners where the patient can pay the prevailing rates."

We fail to note any mention of physicians or medical society in this account. When will the leaders of lay health organizations learn to consult physicians and medical organizations in their plans?

In contrast with Buffalo the physicians of Troy are being consulted in a health movement in this city, according to the following account in the *Troy Budget* of March 22d:

"In the movement to promote and popularize health preservation through annual physical examination, the Rensselaer County Medical Association and the Rensselaer County Tuberculosis Association are co-operating with the National and State Associations in trying to interest the people of Rensselaer County in this subject.

"With its usual sympathy in movements of this kind, Proctor's Theatre is lending its aid, and tomorrow, Tuesday and Wednesday will project the film, bearing the title of 'Working for Dear Life.' The film has been produced by the Metropolitan Association and is being used throughout the United States. More than two million people have already seen it.

"During the past year the Rensselaer County Medical Association has ascertained as far as possible the number of people who are having annual physical examinations in Troy and the county. For the population of our country the number who are giving the prevention side of health work attention is very small. We have adopted the national slogan, 'Have a physical examination in your birthday.' This means go

## GORGAS MEMORIAL

Pursuant with its plan to secure active cooperation between the public and the medical profession the Gorgas Memorial is now holding meetings, open forums, large and small convocations of influential men and women in cities and towns throughout the United States. This is also in line with a \$5,000,000 Endowment Fund appeal now before the public. Staten Island, New York, reports such an enthusiastic reception in that community of the Gorgas Idea that we believe it is worth noting in these columns.

On March 22nd, Sunday afternoon, over one hundred Staten Islanders assembled at the home of Mrs. William G. Wilcox to hear about this health movement which aims to prolong life approximately twelve years and make those years of maturity the best of all, that is healthy, productive years.

We quote from notes taken at that meeting.

"Mrs. William G. Wilcox called the meeting to order and told informally and delightfully about the Gorgas Idea.

"Dr. Edward Sherrard Rimer of New York City was the first speaker. Dr. Rimer said that two of the reasons he was personally interested in the Gorgas Memorial were because he was so fortunate as also to belong to the Society of Bellevue Alumni of which General Gorgas was so distinguished a member. Also Dr. Rimer as a former quarantine officer of Staten Island had formerly himself to combat yellow fever.

"Dr. Rimer made an exceedingly interesting address.

"Briefly, he said that all physicians are interested in preventive medicine. He outlined the life of Dr. Gorgas, showing how it had pivoted around yellow fever.

"Most interesting was Dr. Rimer's description of a Staten Island yellow fever epidemic some years ago. He related that ships coming in from foreign ports brought yellow fever cases and in spite of every precaution then known to medical officers the dread disease spread all over the Island. So enraged were the Staten Islanders at one time when there were 108 cases of yellow fever in St. George (the section where the ferry comes in from New York and also where the quarantine buildings were) that a group of them got together and set fire to the hospital. This deed was reviled in every newspaper in the land, but eventually the courts set free the citizens who had perpetrated it (many of them very prominent socially and financially) on the ground that no special community should be made to suffer for the good of the whole country.

"The irony of the situation was, as Dr. Rimer put it, that 'all this didn't keep the yellow fever mosquito from wandering around' and yellow fever was as rampant as ever!

"Dr. Alva H. Doty, as Health Officer, was at that time very much interested in following the

work of General Gorgas in Havana and Panama. (Dr. Doty is now an enthusiastic member of the Gorgas Memorial New York State Governing Committee). Working on the mosquito theory of yellow fever that Gorgas so marvelously demonstrated, Dr. Doty and his helpers were able eventually to banish yellow fever from Staten Island and an almost worse plague—malaria.

"Quotations of statistics from Health Department Bulletins illustrated the extent of deaths from preventable diseases, and Dr. Rimer pointed out how the Gorgas Memorial expected to remedy this. 'In the United States,' declared Dr. Rimer, 'there are three million persons sick today, of whom one million are wage earners. The financial loss from preventable illness and death amounts to at least one and one-half billions of dollars annually. At least one hundred million dollars of the money lost each year on account of illness could be saved and a quarter of a million deaths could be prevented.'

"Dr. William Bryan, known and beloved by every family in Staten Island, next spoke.

"Two years before, in 1923, Dr. Bryan stated that he had had the honor to be present at the laying of the corner stone of the Gorgas Memorial Institute in Panama. This Institute is the \$750,000 gift of the Republic of Panama for research along the lines of tropical disease. Dr. Richard P. Strong of Harvard is Director of this phase of the Gorgas Memorial. 'Most impressive,' said Dr. Bryan, 'was the ceremony I witnessed when the corner stone of this great Institute was put in place.'

Dr. Bryan, who had been of the party of Dr. Franklin Martin of Chicago on this occasion, spoke of his long association with Dr. Martin, how he loved and admired him personally and how fortunate the Gorgas Memorial was in having such a man as Chairman of its national Board of Directors.

Dr. Bryan told graphically of the difference in Panama as he had seen that country before and after Gorgas's day—Panama under native control and Panama under the control of sanitary laws. Dr. Bryan considered Panama a splendid example of what knowledge and education along health lines can mean. 'The Gorgas Memorial,' stated Dr. Bryan, 'has as its object to spread a more advanced knowledge of what relates to health.'

"'Medicine over the radio, health talks at meetings such as this one at Mrs. Wilcox's home, lectures, easily read pamphlets for wide distribution, the great press and by films in the motion picture theatres—and in schools—are some of the means to be employed by the Gorgas Memorial in promoting better health,' continued Dr. Bryan. 'The medical profession,' he drily remarked, 'is, you will note the only profession that is working to knock the props from under it

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these columns will be made for review as dictated by their merits, or in the interest of our readers.

**PRACTICAL HISTOLOGY** By HENRY ERDMANN RADASCH, M.Sc., M.D. Second Edition Revised and Enlarged 12mo of 621 pages, with 333 illustrations Phila., P. Blakiston's Son and Co., 1924 Cloth, \$5 00

**TOXICOLOGY OR THE EFFECTS OF POISONS** By FRANK P UNDERHILL, Ph.D. 12mo of 292 pages Phila., P. Blakiston's Son and Co., 1924 Cloth, \$2.25

**LANG'S GERMAN-ENGLISH DICTIONARY OF TERMS USED IN MEDICINE AND THE ALLIED SCIENCES** Edited and Revised by MILTON K. MEYERS, M.D. Third Edition, enlarged. Octavo of 613 pages Phila., P. Blakiston's Son & Co., 1924 Cloth, \$7 00

**THE ESSENTIALS OF PHYSIOLOGY INCLUDING THE PHARMACODYNAMICS OF THE IMPORTANT TYPICAL DRUGS** By GEORGE BACHMANN, M.S., M.D., and A. RICHARD BLISS, Jr., A.M., Ph.D., M.D. Octavo of 343 pages with 178 illustrations Philadelphia, P. Blakiston's Son and Company, 1924 Cloth, \$3 50

**A TEXT-BOOK OF PRACTICAL THERAPEUTICS** With Especial Reference to the Application of Remedial Measures to Disease and Their Employment Upon a Rational Basis By HOBART AMORY HARE, B.Sc., M.D., LL.D. Nineteenth Edition, enlarged, thoroughly revised, largely rewritten Octavo, 1061 pages, 144 engravings, 8 plates Phila., Lea and Febiger, 1925 Cloth, \$7 00

**ELEMENTARY MORPHOLOGY AND PHYSIOLOGY FOR MEDICAL STUDENTS** A Guide for the First Year and a Stepping-stone to the Second By J. H. WOODGER, B.Sc. Octavo of 528 pages, illustrated. New York, Oxford University Press, American Branch, 1924 Cloth, \$4.20

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 4, Number 6, December, 1924 (Lahey Clinic Number) Published every other month by the W. B. Saunders Co., Phila. and London Per Clinic Year (6 issues) Cloth, \$16 00 net, paper, \$12 00 net.

**THE PHYSIOLOGY OF MIND** An Interpretation Based on Biological, Morphological, Physical and Chemical Considerations By FRANCIS X. DERCUM, A.M., M.D., Ph.D. Second edition, reset Octavo of 287 pages Phila. and London, W. B. Saunders Co., 1925 Cloth, \$3 50

**PRINCIPLES OF SURGERY FOR NURSES** By M. S. WOLFF, M.A., B.Sc. M.R.C.S. (Eng.), L.R.C.P. (Lond.) Octavo of 350 pages, illustrated. Phila. and London, W. B. Saunders Co., 1925 Cloth, \$3 00

**MEDICAL CLINICS OF NORTH AMERICA.** Volume 8, Number 4, January, 1925 (Mayo Clinic Number) Published every other month by the W. B. Saunders Co., Phila. and London Per Clinic Year (6 issues) Cloth, \$16 00 net, paper, \$12 00 net.

**TEXT-BOOK OF HUMAN PHYSIOLOGY INCLUDING A SECTION ON PHYSIOLOGIC APPARATUS** By ALBERT P. BRUBAKER, A.M., M.D., LL.D. Eighth edition, revised and enlarged Octavo of 853 pages with 367 illustrations. Phila., P. Blakiston's Son and Co., 1925 Cloth, \$5 00

**ORGANIC MEDICAMENTS AND THEIR PREPARATION** By ERNEST FOURNEAU Authorized translation by W. A. SILVESTER, M.Sc. Octavo of 262 pages with 22 illustrations Phila. P. Blakiston's Son & Co., 1925 Cloth, \$4.25

**MEDICINE AN HISTORICAL OUTLINE.** By M. G. SEELIG, M.D. 12mo of 207 pages Baltimore, Williams and Wilkins Co., 1925 Cloth, \$2.25

**PREPARATION OF SCIENTIFIC AND TECHNICAL PAPERS** By SAM F. TRELEASE and EMMA SAREPTA YULE. 12mo of 113 pages Baltimore, Williams and Wilkins Co., 1925 Cloth, \$1 50

**THE DETERMINATION OF HYDROGEN IONS** An elementary treatise on the hydrogen electrode, indicator and supplementary methods with an indexed bibliography on applications By W. MANSFIELD CLARK, M.A., Ph.D. Second Edition Octavo of 480 pages Baltimore, Williams and Wilkins Co., 1925 Cloth, \$5 00

**THE INHERITANCE OF MENTAL DISEASES** By ABRAHAM MEYERSON Octavo of 336 pages Baltimore, Williams and Wilkins Co., 1925 Cloth, \$5 00

**SERUM DIAGNOSIS OF SYPHILIS BY PRECIPITATION** Governing Principles, Procedure and Clinical Application of the Kahn Precipitation Test. By R. L. KAHN, M.S., D.Sc. Octavo of 237 pages Baltimore, Williams and Wilkins Co., 1925 Cloth, \$3 00

**CLINICAL PSYCHOLOGY** By LOUIS E. BISCH, M.D., Ph.D. Octavo of 346 pages, with illustrations Baltimore, Williams and Wilkins Co., 1925 Cloth, \$3 00

**ELEMENTS OF PHYSICAL BIOLOGY** By ALFRED J. LOTKA, M.A., D.Sc. Octavo of 460 pages, illustrated Baltimore, Williams and Wilkins Co., 1925 Cloth, \$5 00

**LES ARYTHMIES EN CLINIQUE** PAR A. CLERC, PROFESSEUR AGREGÉ A LA FACULTE DE MEDECINE MEDECIN DE L'HOPITAL LARIBOISIERE. Preface du Pr H. VAQUEZ Masson et Cie, Editeurs Paris 1925 34 fr

**FROM INFANCY TO CHILDHOOD** The Child from two to six years By RICHARD M. SMITH, M.D., Assistant Professor Child Hygiene, Harvard University The Atlantic Monthly Press, Boston 1925

**DISEASES AND DEFORMITIES OF THE FOOT** By JOHN JOSEPH NUTT, B.L., M.D., F.A.C.S., Professor Orthopedic Surgery, Polyclinic Medical School and Hospital, Surgeon-in-Chief, New York State Orthopedic Hospital for Children. Second Edition, completely revised E. B. Treat & Co., New York, 1925 Price, \$4 00

**THE PRACTICAL MEDICINE SERIES**, comprising eight volumes on the year's progress in medicine and surgery Under the General Editorial Charge of CHARLES L. MIX, A.M., M.D. Volume V, Gynecology and Obstetrics Series 1924 The Year Book Publishers, Chicago Price, \$2 00

**LA REACTION DE FIXATION DANS LA TUBERCULOSE** PAR ARCHILLE URBAIN Preface De A. BESREDKA, Professeur A l'Institut Pasteur Masson et C, Editeurs Libraires De L'Academie De Medecine, 120 Boulevard Saint-Germain, Paris, 1925

to your own family physician and enlist his aid in preserving your present health or correcting any undesirable conditions which may exist "

The New York Sunday *Times* of March 22d, contains an article on Motor Camps. It had investigated camps in various parts of the country, and described one in Michigan maintained at an annual cost of \$3,000 to the public treasury, the theory being that the campers would spend money in the town. The reporter had canvassed the campers, 167 in number, and found that the total amount that they had spent that day was nine dollars, and that less than 5 per cent of them expected to patronize a hotel during a lengthy trip.

The article states that a fee is now being charged for some camps, and says

"The recently organized International Association of Tourists' Camps was formed to direct in an advisory capacity the general management and equipment of motor camps in the United States and Canada. One of its prime objects is to abolish the free municipal camping system, substituting better equipped camps at which a nominal fee will be charged.

"Competition by various communities for the expectant trade from motor visitors, which it is now discovered seldom materialized, had the result that many desirable comforts were obtained for nothing.

"Many of these places," explained President McManus at the recent organization of the association, "are equipped with electric lights, water sanitation, tables under shelter, fireplaces, fuel for cooking, police protection, and in many instances local evening papers are supplied and shower baths provided, all gratis to campers, but at the expense of taxpayers."

"The large free tourist camp at Denver, which has been used by thousands of motorists, was recently changed to a pay-as-you-enter camp and hundreds of other western camps will adopt that policy this year."

Motor camps are a potential source of danger to health, and our experience is that the sanitary attitude of any set of campers will bear watching.

The New York *Herald-Tribune*, March 26th, contains the following account of the arrest of a chiropractor.

"Joseph Miller, a chiropractor of 49 Seventh Street, was held in \$500 bail for trial in Special Sessions yesterday, on a charge of practicing

medicine without a license. He was alleged to have treated John Sankovski, 316 Sixth Street, diagnosing pulmonary tuberculosis as acidity of the stomach.

"Sankovski was a registered patient with the Board of Health. Dr. Samuel H. Paley, of the Health Department, said he and other doctors had examined Sankovski and were arranging to send him, at the city's expense, to a dry climate. Dr. Paley added that on a recent visit Sankovski denied having tuberculosis, and gave Miller as his authority.

"On the stand Sankovski said Miller had promised to cure him for \$40, which he paid. The cure consisted, he told Magistrate Oberwager in Essex Market Court, of manipulation of the spine and prescription of certain foods."

We presume that chiropractors are doing this same thing in every community, but who will assume the burden of their prosecution? Here is a strong argument for the Medical Practice Act, which was defeated in the last Legislature.

The New York *Times* of March 29th quotes Dr. W. H. Park in his criticism of the Medical Reference Bureau, which seems to exist in order to oppose vaccination and the use of serums. The article says

"That is an organization that has been putting forward the most horrible statements. The death rate has been cut tremendously by diphtheria antitoxin, which is a most efficient remedy. There were 1,200 deaths from diphtheria in 1919, for instance, and this year only about 500.

"The discouragement is not felt about the remedy itself, which is of remarkable efficacy, but it is felt because of the fact that, with this wonderful remedy in existence, so many parents fail to have their children treated until it is too late. To illustrate, we had a woman bring four children to the Willard Hospital with diphtheria a few days ago.

"One had had it four days, two had it two and one-half days and the other one day. The child that had the disease for four days died fifteen minutes after his arrival.

"I believe, and I have said, that in time the death rate from antitoxin will be reduced by 90 per cent, but I doubt if the final 10 per cent of the cases can be prevented because of the seeming impossibility of carrying public health education to the point where one of our greatest remedies is thoroughly used. Both the antitoxin and the immunization methods are extremely effective agents in warring on this disease."

## SOME PRACTICAL CLINICAL AND CYSTOSCOPIC POINTS IN UROLOGICAL DIAGNOSIS \*

By MAXIMILIAN ZIGLER, M D,

NEW YORK CITY

IN making urologic diagnoses one finds that the past history, clinical symptoms, physical and cystoscopic examination, the laboratory and X-ray pictures are all necessary for the proper work-up of a case

Cystoscopic examination of the bladder or ureteral catheterization does not necessarily mean making a correct diagnosis. One must have a complete history of the case plus physical examination before going ahead with the cystoscopic examination. Because then one already will have an idea as to the tentative diagnosis. Yet we have the very frequent experience of having one of our confreres trying to make an appointment with us for cystoscopy only. Just as if that one method of examination were the complete story.

In the physical examination it is important to know whether the meatus is patent. A narrow meatus either congenital or acquired is not an infrequent complication. This slight complication if not noticed until one is ready to perform cystoscopy will be a source of inconvenience and loss of time to the surgeon.

A narrow meatus is not an infrequent condition in both males and females. It is surprising how often a narrow meatus may be present and yet give no symptoms. On the other hand I have seen a number of cases where very marked and many urological symptoms were present as a result of a narrow meatus.

The history of urological patients must involve the past as well as the present history of infections. Tuberculosis plays a very important role in urology. This makes it necessary to go into the minutest details, as to the past personal history of the patient in regard to pulmonary tuberculosis, pleurisy or pneumonia.

In taking histories of patients one must never forget that a great many patients are determined to live down tuberculosis. They feel there is a stigma attached to either of the above named

infections, and they try to forget the same. So that if you inquire the past history of such an infection the patient promptly denies the same. Feeling that the present trouble has no relationship to the past infection, so why tell. This spirit often results disastrously for the patient for it helps to conceal the diagnosis in a difficult or in an early case.

Another infection that plays a very important part in urology is the colon bacillus. In the history it is advisable to inquire if the patient has a tendency toward constipation because not infrequently a severe acute colon infection takes place in the kidneys after a marked attack of constipation. It is also important to inquire whether the patient ever had an attack of pyelitis during pregnancy, infancy, or childhood. Colon bacillus infection of the kidney or pelvis is very apt to develop after exposure to wet or cold especially after excessive indulgence in alcohol.

Besides going into the history of tuberculosis and colon bacillus infection, it is essential to go into the venereal history. After the history as to past infections has been gone into, one should inquire whether any foreign bodies have been introduced into the urethra especially in a vague and puzzling case. Although at times it is difficult to elicit such a history as the following cases will prove. Called by a confrere to see a 60-year-old man. His doctor simply wished me to see him in order to verify his diagnosis of an inoperable prostatic carcinoma. Examination disclosed a hot fluctuating tumefaction around the bulbous urethra. Prostate normal. Patient had a high temperature and was on the point of retention of urine. The diagnosis of peri-urethral abscess of unknown etiology was made. A large abscess was incised and as my finger reached into the pus pocket a sharp object was encountered and on withdrawal it was found to be a tooth pick. Patient confronted with tooth pick denied having introduced the same for sexual gratification. Says that he probably sat on the

# BOOK REVIEWS

**ANESTHESIA FOR NURSES** By COLONEL WILLIAM WEBSTER, DSO, M.D., CM Professor Anesthesiology, University of Manitoba Medical School. Illustrated C V Mosby Co, St Louis 1924 Price, \$2 00

The book covers the subject as fully as is necessary. In fact, the great question in this subject, as in many others, is how much instruction should be given the nurse. A certain amount of the medical aspects of anesthesia must be introduced in a book to lead up properly to the nursing considerations, while points in technique of administration are outside of the field.

Dr Webster, already the author of a book on anesthesia for general medical service, has used his wide experience in selecting the material necessary for a book of this sort. The practical considerations involved in the nursing care before and after the operation, with emphasis on the mental preparation of the patient, are stressed, and the dangerous events in the course of the operation and at the later time when the nurse is in charge are fully explained. The practical aspect of the case is well covered with careful explanation of the remedial agents to meet any emergency which may arise.

GEO W TONG

**CLINICAL STUDIES IN EPILEPSY**, composed of clinical notes on some epilepsies as bearing on the pathogenesis of idiopathic epilepsy. By DONALD FRASER, M.D., FRFP & S (Glas). William Wood & Co, New York, 1924 Price \$2 50

The scope of this book is thus set forth by the author: "I purposely avoided dealing with questions of heredity, treatment, and the general pathology of epilepsy, being concerned mainly with the meaning and mechanism of the fit in its beginnings as a cerebral process." His effort is to discover some unknown hormone which he postulates as an important factor in resisting the influence of toxin or toxins which initiate the epileptic movement.

From clinical material accumulated in over thirty years' experience he shows the relation of epilepsy to psychology, vaso-constriction, the cerebro-spinal reflex, the endocrine glands, traumatism and tumors, tuberculosis and syphilis, and arrives at the theory that the induction of an epileptic seizure of any kind is due to two main factors "these are a toxin or toxins, whether or however produced, noxious to cell or vessel, and a cerebro-spinal or cerebral reflex set up by the irritation of strain or defects in parts or centres serving special functions."

The book is a stimulating contribution to the slowly accumulating knowledge of this most obscure and terrible of diseases.

ROBERT ORMISTON BROCKWAY

**OUTLINES OF INTERNAL MEDICINE FOR THE USE OF NURSES AND JUNIOR MEDICAL STUDENTS** By CLIFFORD BAILEY FARR, A.M., M.D. Fourth and revised edition. 12mo, 377 pages, 69 illustrations, 6 plates. Phila and New York, Lea & Febiger, 1924. Cloth, \$2 75

This is a comprehensive high grade book and covers the subjects treated in a satisfactory manner. As stated in the preface the book is divided into ten parts, eight of which are devoted to diseases of the various systems and two to harmful agencies invading the body from without.

All the articles are well written with printing paper and illustrations of the highest type. The volume is of handy size and handsomely bound.

The volume is intended principally for a text and reference book for nurses and is heartily recommended for first class training schools.

W E. McCOLLOM

**AFFECTIONS DE L'OEIL EN MEDECINE GENERALE—DIAGNOSTIC ET TRAITEMENT** By Professors F TERRIEN AND G COUSIN. Masson et Cie, 120 Boulevard Saint-Germain, Paris 1924

This work by F Terrien and G Cousin considers affections of the eye in the relation to General Medicine, mainly associating the diagnosis and treatment.

There are chapters on the anatomy and physiology of the eye, which, though brief, are sufficiently complete to meet the purpose of the outlines.

The pen and ink illustrations are well executed and illustrate the points under discussion satisfactorily.

The section on examination of the eye is presented in a practical way and gives a succinct survey of the aspects of direct and indirect vision. Color sense and the light sense are touched upon.

The neurological aspect of the subject is well developed, particularly as expressed in motor anomalies.

The semiology is expanded in a section wherein the authors progress in a systematic order to unfold the ocular manifestations of systemic disease. In this portion of the book many photographs are inserted which are of distinct value. The last few chapters take up the manifestations related to the endocrines, cardiovascular system, respiratory apparatus, etc. Separate diseases are discussed under these heads, especially valuable being that portion dealing with the nervous system. As a whole the book seems very worthy of translation.

J N E

**CLINIQUE MEDICALE DES ENFANTS—AFFECTIONS DE L'APPAREIL RESPIRATOIRE.** P NOBECOURT, Professeur de Clinique Medicales des Enfants à la Faculté de Médecine, de Paris. Masson et Cie, Editeurs, Paris, France, 1924

This is a collection of Clinical Lectures by Professor Nobecourt many of which have been published separately in the various French medical journals. Nobecourt is one of the best known pediatricians not only of France but of all Europe and he has the happy faculty of being a clear and concise clinical teacher. The fact that the various chapters were each clinical lectures makes them very lucid and profitable reading.

Chapters of particular interest are those on Asthma, Whooping Cough and Tuberculosis, Pleura and Lungs in Cardiopathies, and on the various forms of Pleurisy in Children. One notes the frequent references to the tracheo-bronchial glands in the text as is so much more the case with European than with American writers on Pediatric subjects. This work is worthy of its author and his publishers, which is saying a great deal.

WM HENRY DONNELLY

**HISTORY OF THE GREAT WAR BASED ON OFFICIAL DOCUMENTS—MEDICAL SERVICES. GENERAL HISTORY. Vol 2.** By Major-General Sir W G Macpherson, K.C.M.G., C.B., LL.D. Octavo, 510 pages, illustrations and maps. London, His Majesty's Stationery Office. Cloth, 21s. net.

This volume of the History of the Great War presents in detail the problems of the care of the sick and wounded by the British Expeditionary Force in France and Belgium. It is a complete, thorough study which gives in detail the medical activities as they were met in a general way and also the care of the wounded during and after each battle. For any one interested in the problems of medical activities in war, this volume holds a wealth of information. The thoroughness and detail of the work makes it a historical volume. Excellent maps of the battle fields are given throughout the book.

H M M

ent from either tubercular testicle or the syphilitic testicle. Gonococcus infection of the testicle is still called epididymo orchitis in many text books. On careful examination of the testicle during operation or after the subsidence of the acute stage, one will find that there is no involvement of the body of the testicle, that the large size of the testicle is due to the enormous enlargement of the epididymis, the epididymis not infrequently, being as large or even larger than the body of the testicle. In addition, there is an inflammation and oedema of the tunica vaginalis with some accompanying hydrocele, plus some edema of the other layers of the testicle. Furthermore, when the acute inflammation has subsided, one can readily palpate the thickened, knoblike epididymis as the only remaining lesion, while if one palpates the body of the testicle one will find it perfectly normal. In other words, gonococcus inflammation of the testicle is not an epididymo orchitis but an epididymitis.

The second type of inflammation of the testicle is that due to staphylococci and colon bacillus. This type of epididymitis usually occurs in patients who have infections of the bladder, prostate or posterior urethra. This infection not infrequently is a post-operative complication following prostatectomy, lithopaxy, hernia operation, etc.

The clinical symptoms of the staphylococcus-colon bacillus group of epididymitis are not very different from the gonorrheal type except as a rule the swelling and pain in the testicle is not apt to be as acute or severe in the former as it is in the latter type.

The history of the tubercular testicle is usually a chronic one. Very exceptionally a patient may have an acute tuberculosis of the testicle. Occasionally the infection is subacute. The subacute case comes to the office complaining of a lump and a slight pain in the affected testicle. Examination shows slight enlargement of the epididymis. The patient is not as acutely ill as he is in either gonococcus or the mixed infection epididymitis. The chronic type of tubercular testicle is the usual one. History is somewhat as follows. The patient states that he has been struck on the scrotum and then for the first time feels a lump in the testicle, or while taking a bath discovers a lump in the same, or during a routine physical examination this lump is discovered. In addition to noting this lump some patients have slight pain in the testicle, some in addition have slight discharge from the urethra. This latter symptom is quite important and is emphasized because not infrequently a young boy with discharge plus tuberculosis of the epididymis is accused both by his parents and by his doctor of having gonorrhea. In fact, a great many of these cases are treated for gonorrhea for a considerable time and are really made worse by strong chemical and drastic mechanical methods. In urology,

it is important to remember that chronic tuberculosis is stirred up into acute or subacute process by strong Agnoz treatment or by passing sounds or instruments on such cases. In fact, we use this point as an aid to diagnosis and make the following rule that whenever the reaction following instrumentation on the urethra, bladder or prostate is out of proportion to the instrumentation, suspect tuberculosis.

As a rule, the tail of the epididymis is involved in an adult in an early case of testicular tuberculosis. Usually the entire epididymis is involved before the patient comes under observation. The urologist not infrequently sees the case when the entire testicle is involved, with sinus formation well marked. A differential point of diagnosis between adult and early childhood testicular tuberculosis is that in adult life, as just mentioned, the early process is in the tail of the epididymis, while in childhood it is more apt to be located in the body of the testicle. Palpation of the typical tubercular epididymis in the adult will disclose a nodular epididymis, especially the tail. This is considered characteristic. At times, either thickening or nodulation of the vas on the affected side is present. I have found thickening of the vas much more frequently present than nodulation. In fact, neither thickening nor nodulation of the vas have in my experience been present as frequently as one would suppose from reading the literature. In addition to these physical signs the diagnosis of tuberculosis of the epididymis is materially aided by finding an associated prostatitis and seminal vesiculitis of the indurated or the nodular type.

I believe that induration or nodulation of the prostate or seminal vesicles is a more frequent accompaniment of tubercular epididymitis than is induration or nodulation of the vas. In other words, as far as palpation is concerned, I feel that the half-way house, the vas, situated between the epididymis and the prostate and seminal vesicles is less frequently involved than either the epididymis or the prostate and seminal vesicles. If the vas be found thickened it is a definite aid in the diagnosis of genital tuberculosis.

Additional aids in the diagnosis of genital tuberculosis are either sinus formation in the testicles, or physical signs of tuberculosis elsewhere in the body, especially in the lungs. As further aids to the diagnosis of urological tuberculosis are the various laboratory methods. Examination of the urine for tubercle bacilli and guinea pig inoculation, the latter being very much more reliable because of the difficulty of finding the tubercle bacillus in the urine. The disadvantage of guinea pig inoculation is the fact that one must wait about six weeks for a report.

Various authors speak of sinus formation as occurring only in tuberculous epididymitis. I have reported a case of bilateral gummatous epi-

tooth pick but does not know when This case shows how difficult it is to obtain a good history

After a thorough history has been taken one proceeds to the physical examination We usually examine the external genitals first Taking note of the appearance of the same, especially whether there are any anatomical abnormalities such as hypospadias, narrow meatus, false openings, split meatus, etc Then the external genitals are inspected for lesions and the urethra for discharge

Under inspection allow me to quote the following We have had a number of female patients referred to the urological clinic at Lebanon who had frequency of urination as their chief complaint, in whom on inspection before a cystoscope was passed a diagnosis of their condition was made A good example is the following Patient had an eczematous, bluish, shiny, somewhat indurated eruption on the vulva, extending down the buttocks on to the inner surface of the upper thigh This skin condition was diagnosed as diabetic eczema, and the symptom of frequency as being due to diabetes This diagnosis was made prior to urine examination, and was subsequently confirmed by the finding of sugar in the urine and by negative cystoscopic examination Another type of case in which invariably we explain urologic symptoms by inspection is cystocele and rectocele We have seen a considerable number of such cases and have found them negative from the urologic standpoint Inspection gave us the diagnosis

Urethral caruncle in women usually located at the meatus may extend bladderward for about a half inch Inspection will draw your attention to this condition Unless you actually attempt, however, to pass a fair sized sound you can have no idea as to the amount of obstruction the same may cause

After inspection we proceed to palpation We palpate scrotal sac to ascertain if both testicles are present, also to ascertain their size, consistency, etc If enlargement of testicles be found one must differentiate between epididymitis, hydrocele and tumor Both cords are palpated for thickening or inflammation and also for varicocele If bilateral varicocele be found one must think of the possibility of growth in the pelvis or abdomen

After the fifth decade if the patient gives a history of having had warts on his penis for years or a tight foreskin associated with balanitis and develops a lesion, think of epithelioma, especially if the growth has been of slow formation

In the physical examination of the abdomen, special notice is taken if kidneys be movable, prolapsed, enlarged or tender Deep fist percussion over both kidneys, the so-called Murphy sign, is a valuable sign of kidney disease, especially calculous After the physical examination, the patient is requested to void urine and

the macroscopic appearance is noted whether clear, pus cloudy or bloody Twenty-four hour specimen is then sent to laboratory

After performing all the above mentioned preliminaries, one is ready for cystoscopy If there is considerable discharge, especially if purulent, it is not advisable to perform cystoscopy On the other hand if hematuria be present that is the best time to perform cystoscopy, because if one waits until the bleeding stops, one may not be able to find the site of bleeding

Cystoscopic examination of the bladder sphincter of females complaining of frequency as their only symptom, not infrequently will show cystic degeneration of the bladder neck These are the patients whom we used to call "female urinators," for want of a better name, because we did not know the cause and considered the condition as a symptom of a neurotic woman These cases of cystic degeneration of the bladder neck are curable with fulguration combined with dilatation and Agnoz instillation

Until very recently it was not generally known that gonorrheal stricture of the female urethra is quite a prevalent condition and may give a number of urologic symptoms Its usual site is at the meatus It may, however, extend from the meatus all the way back to the bladder Another interesting cystoscopic point in women is that trigonitis is a very prevalent condition, in fact very much more frequent than in men, in spite of the fact that males so frequently have inflammation of their posterior urethra

We will now take up some of the interesting points about genital and also urinary tuberculosis I have purposely not used the frequently misused term, genito-urinary tuberculosis Patients may suffer either from genital tuberculosis, urinary tuberculosis, or the combination of the two, namely, genito-urinary tuberculosis With the modern methods of diagnosis we can as a rule readily place patients in a definite group and are not obliged to use the indefinite term genito-urinary tuberculosis

In a diagnostic study of testicular inflammation, the past history of the patient, as previously mentioned, is essential In dealing with epididymitis there are usually four different bacterial groups to be considered The first is gonococcus, the second mixed infection comprising staphylococcus and colon bacillus, the third tubercle bacillus, and the fourth spirochaete pallida In the gonococcus testicle we usually obtain the history of gonorrhea, either present or past There may be a discharge with or without gonococci demonstrable Onset usually sudden with great pain, acuity, marked swelling and redness of the testicle The testicle is swollen to two or three times its normal size Pain usually so severe that the patient is obliged to go to bed unless the testicles are properly strapped and lifted upon the pubic bone This acuity of symptoms is entirely differ-

of the bladder Usually an ordinary papilloma has a very slender stalk and a slender base with a distinct blood vessel coursing through its center, while malignancy usually has a broad base Secondly, a profound cystitis usually accompanies malignancy, while the bladder is usually clean with papilloma Bullous or cobble stone edema is a not infrequent accompaniment of malignancy, but is not present with papilloma Marked incrustation of the growth, usually phosphatic, is a not infrequent satellite of cancer of the bladder, so much so that a great number of these malignant tumors with incrustation are diagnosed as bladder calculi

In searching for bladder tumors with the cystoscope be sure to not alone look at the usual site, namely the trigone, but also make sure to look up at the vault of the bladder, especially the roof of the bladder sphincter, because occasionally a tumor is located at that site

Occasionally a bladder tumor can be diagnosed by palpation of the base of the bladder through the post prostatic recto-vesical space That is, one can feel induration of the trigone by palpation with the finger in the rectum Sometimes bimanual palpation is an aid in diagnosis The one finger in the rectum palpating the base of the bladder, the other hand pushing the bladder down into the palpating hand Personally I have found this examination negative in most of the cases, even where cystoscopy revealed extensive involvement to the trigonal region, a region which should be very easily palpable through the rectum Prostatic carcinoma on the other hand I have found to be easily detected by palpation This is probably due to the fact that the lobe usually involved is the posterior, which is nearer to the palpating finger than is the trigone

Occasionally the diagnosis of malignancy of the bladder can be made by seeing pieces of the growth in the urine voided These pieces are shreddy flesh like masses which have come away from the tumor Not infrequently some of these pieces may remain attached to the cystoscope These pieces may be sent for diagnosis to the laboratory

In snipping pieces of the growth by means of the rongeur for diagnosis, be sure that you snip from the base of the growth, as the tip or papillomatous stalk may show benign growth only You not only must make sure to take a punch well down into the base of the growth, but also take pieces from various areas, because some areas may not be malignant while others will show characteristic cancerous involvement

#### PROSTATIC HYPERTROPHY

Patients suffering from so-called prostatic hypertrophy must be carefully studied clinically as well as cystoscopically Hypertrophied prostate usually occurs in middle or advanced life.

Such a patient usually gives a history of gradually increasing nocturia for a number of years

However, given a case in which the whole history of symptoms is only of short duration but nevertheless quite marked symptoms, one can suspect trouble other than hypertrophy and most likely malignancy

A prostatic with medium size obstruction who is voiding fairly well suddenly gets up retention What is the usual explanation? The explanation is the same as that for a patient with a stricture of the urethra of size 20 to 24 Fr who suddenly develops retention The stricture case develops an acute edema on top of a stricture of 20 to 24 Fr closes off the urethra to almost nothing, so that no urine can come through The same is true of the prostatic case Due to constipation, getting wet feet, alcohol or sexual overindulgence, an acute edema takes place within the region of the prostatic hypertrophy and causes retention After the acute edema passes, you will be able to pass the same size instrument that you could have passed prior to the retention

There are some urologists who have recently stated that cystoscopy is contra-indicated in the old men with prostatic hypertrophy as there is too much trauma, shock, bleeding, etc., and also because you can diagnose without the cystoscope by clinical symptoms that the patient probably has an hypertrophied prostate This line of argument is not tenable because, should any untoward complication occur as the result of cystoscopy, you can always go ahead and perform supra-pubic drainage Also, we have all seen cases where the finger in the rectum showed a normal prostate and the cystoscope showed marked intra-urethral encroachment or intra-vesical prostate protrusion In other words we know since the advent of the cystoscope that a prostate may enlarge in any one of three or all three directions, that is intra-rectal, intra-vesical, or intra-urethral The surgeon also should know what complications or associated conditions may be present in the bladder, such as stones, diverticula, new growth, etc., also whether the prostate be a small, hard, fibrous or a large, adenomatous prostate These points he must know in order to decide the route he will take, whether the supra-pubic for the latter or the perineal for the former I believe a surgeon who does not avail himself of these advantages is working in the dark

As soon as the diagnosis of a fair size stone in the bladder is made the tendency for the average surgeon who can do lithopaxy is to crush the stone, without studying the conditions associated with that stone, with the result that the condition that caused the stone will soon cause a recurrence of calculus formation Such a case should be studied carefully cystoscopically before doing lithopaxy, in order to know whether there is an associated prostatic obstruc-

didymitis with sinus formation. However, sinus formation in other than tuberculous epididymitis is the exception rather than the rule.

In the syphilitic testicle one usually has at the outset involvement of the head of epididymis. This inflammation, as a rule, is of a chronic type. Not infrequently there is an associated hydrocele. This hydrocele is usually small. Occasionally we get what is called the oyster shell testicle, which is characteristically syphilitic. Diagnosis is at times quite difficult. At times the diagnosis is aided by the past history, by signs of syphilis elsewhere, by positive Wasserman of the blood and finally by the therapeutic test.

#### URINARY TUBERCULOSIS

In the days prior to cystoscopy we used to think that bladder tuberculosis was primary in most of the cases. Today, because of cystoscopy, we know that primary bladder tuberculosis is really an unusual condition. That is, we know that tuberculosis is usually primary in the kidney and secondary in the bladder. The usual clinical symptoms of renal tuberculosis are increased frequency of urination, especially nocturia, painful urination, tenesmus and at times hematuria. This constant desire to urinate with frequency as often as every fifteen minutes, accompanied by severe burning and pain on urination, continued for months or years, makes a pathetic, never-to-be-forgotten picture. Urine may show pus, blood and tubercle bacilli.

Cystoscopically the characteristic points for emphasis are the following. The patient not infrequently has a contracted bladder, especially if his tuberculosis is advanced. This contracted bladder manifests itself clinically by the patient voiding as often as every fifteen or thirty minutes day or night or day and night, voiding but 2 drams to half ounce each time. Cystoscopically one finds that as soon as the above mentioned quantity of fluid is allowed to flow into the bladder, the patient develops terrific spasms, with pain, straining and contraction on the cystoscope, so much so that one must allow the fluid to flow out and with warm solution try to refill slowly. This procedure may have to be tried any number of times before one is able to get a fair degree of distension of the bladder. At times it is almost impossible to get enough tolerance of the bladder for a fair visual field, and by sending such a patient away to the country for a rest for a time, he may return with a tolerant bladder, and an examination may be possible. This lack of distensibility of the bladder, combined with the rapidly accumulating pus mucus and blood, make cystoscopy at such times next to impossible. This peculiar reaction of the bladder to distension, as described above, is characteristic of bladder tuberculosis. There is only one other condition in which contraction of the bladder acts in a somewhat similar manner only, as a rule, not nearly as severe, and that is in bladder malignancy,

especially if the growth is located on the bladder sphincter. In cases of contracted bladder we find that warm solutions are better borne than are cold, also that the bladder is more tolerant to slow filling solutions than to rapidly filling ones. Sometimes a hypodermic of morphine and belladonna will aid the examination. At times novocain 1 per cent injected and forced by the external cut off muscle will help make the examination easier. If other methods fail, sacral anesthesia is ideal.

There are three common types of tuberculosis of the bladder as viewed cystoscopically. First, ulceration around an ureteral opening, second edema around an ureteral opening, third scattered miliary tubercles anywhere in the bladder. The first two types, namely ulceration or edema, are the most common types. I have found the ulcerative type of very much more frequent occurrence than the edematous type. At times there is a combination of edema and ulceration around the ureteral opening. The usual appearance of the ulcerative case is a marked redness around the one or both ureteral openings, with shaggy, roughened edges, excavations and ulcerations making it at times impossible to find the ureteral opening.

At times one does not find the typical ulceration around the ureteral mouth but instead one finds numerous, hemorrhagic, irregular, blotchy like areas, scattered irregularly over the bladder mucous membrane.

The miliary type of bladder tuberculosis is very rare and the cystoscopic picture is the same as tubercles elsewhere in the body. At times creosote pill grains one up to grains ten T I D, causes a very marked specific improvement in the urinary symptoms. Most of these cases are very much irritated by either urotropin or salol.

#### MALIGNANCY OF THE BLADDER

Some urologists consider ordinary papilloma as malignant because of their tendency toward recurrence. This feeling has, however, not been so marked since fulguration has been developed to such a high degree of efficiency. We shall discuss only real malignant bladder tumors. In studying malignancy of the bladder cystoscopically the first thing one is impressed with is that here also as in tuberculosis one has to deal with a contracted bladder. As previously mentioned, I believe that most of the malignancy of the bladder cases can hold more fluid than is possible in the tubercular bladder. The malignant bladder, in addition to being contracted, also shows a marked tendency toward hematuria which is possibly aggravated by the distension and the manipulation of the cystoscope. This contracted bladder symptom, plus the marked hematuria, add greatly to the difficulty of the cystoscopist.

The following are valuable differential points of diagnosis between papilloma and malignancy.

## SCHISTOSOMA HEMATOBIIUM INFECTION AND ITS RELATION TO PERSISTENT URINARY SINUS \*

By WINFIELD SCOTT PUGH, B S, M.D.,

NEW YORK CITY

### INTRODUCTION

CASES of schistosoma infection of the urinary tract have been reported in this country on several occasions. I am sure, however, that many other persistent urinary lesions have appeared in our midst that were undoubtedly caused by this parasite, these cases passing through many hands, often without recognition. We are no longer isolated from the original habitat of this trematode, and as a result of our increasing relations with tropical countries, must expect to find it with greater frequency. During the past twenty years I have seen twenty-one cases of schistosoma infection, six of which were in this country. The disease might be called rare, in this part of the world, but we must always bear it in mind as a possible etiological factor in urinary disease. This remark is particularly applicable to those of us who see many patients from tropical countries.

### DISTRIBUTION

Writers on tropical medicine give the chief source of the disease as Africa, some stating that it is particularly prevalent toward the southernmost part, as the Transvaal and adjacent sections. Others believe it to be more prevalent in the northern section, as in Egypt and its immediate vicinity. Mesopotamia is also given as a point of frequent infection, and some investigators have found the disease in Western Australia. In the Americas, it has been reported in Brazil and we have seen several cases in the Panama Canal Zone.

### ETIOLOGY

In schistosoma infections we have to consider the possibility of three forms of the parasite. The schistosoma hematobium, which is the more frequent in urinary infections, the schistosoma mansoni of intestinal involvement, and the schistosoma japonicum. The latter, at times, wanders into the intestinal tract, but as a rule is satisfied with the production of cirrhotic manifestations in the liver. Among students of tropical medicine the term bilharziosis is usually applied solely to the infection with the schistosoma hematobium, or the urinary form. The three different forms of this trematode are usually sharply limited to the spheres above noted, although schistosoma mansoni has been reported in urinary lesions. We have never seen the latter in the urine nor have any of my friends in tropi-

cal countries, and I am inclined to believe the cases reported were really those of an unusual form of the schistosoma hematobium.

### THE INFECTION

The exact mode of infection is not definitely known, but it is noteworthy that these conditions usually occur in countries where the natives run around barefooted and have the habit of depositing their excrement in whatever place is handy. This suggests a lesion similar to that of early uncinariasis, and we do know that skin itch is common in these countries. Infection through both skin and mucous membrane is suggested by Neatby.

In whatever way the infection occurs we do know that the ova reach the portal system of veins and in this location develop into the adult worms. In the schistosomum hematobium, the ova finally reach the venules of the bladder and then gradually work their way into the bladder submucosa, as the ova is strongly attracted toward anything that resembles water. When the ovum finally reaches real water its capsule ruptures and the so-called miracidium floats free. If it fails to find a suitable host within twenty-four hours, it dies.

Leiper, of the London School of Tropical Medicine, believes that the intermediary host are certain fresh water snails which are found in considerable numbers in the irrigation canals of Egypt and similar places. This author states they also reach what corresponds to a liver in the snail, and the parasite in this stage looks something like a tadpole. In this shape they leave their intermediary host to enter any suitable definitive host.

### SYMPTOMS

The initial symptoms of the disease are never referable to the urinary tract and appear first in a month to six weeks, rarely as long as two months after the infection. Anemia with loss of weight and strength and a dry, scaly skin are common. Early in the disease we also note a leucocytosis of moderate degree with a well-marked eosinophilia.

The urinary symptoms appear in a few days to a week later and usually consist of frequency and painless hematuria, while some cases develop a slight strangury. Several authors tell us that bleeding and dysuria usually cause the anemia, but in the cases we have seen, the anemia was present early in the disease. In some instances of marked hematuria the pain has been noted as excessive, and excessive bleeding is usually

\* From the Urological Department (James Buchanan Brady Foundation) of the New York Hospital.

tion and how extensive the same really is, because it is quite likely that if the prostatic obstruction is of quite a severe degree the enucleation is of paramount importance and not the crushing. In other words, one must get rid of the cause. Also, the cystoscopic picture will give you a good guide as to whether the stone is or is not crushable. The white stones usually are phosphatic and are readily crushable while the dark or black stones are usually oxalate stones and are too hard to be crushed.

### TABES

Tabes, from the urological standpoint, offers some very interesting points in diagnosis. A very early and valuable sign is the loss of sphincteric anal contraction. When the finger is introduced into the normal rectum one finds that one has to overcome resistance to enter, but in tabes one often gets a very early sign of this loss of sphincteric and contraction. It seems as though the finger falls into the rectum, there being no resistance to overcome. This is one of the earliest signs of tabes. A case in point is the following: Patient about 55 years old referred to me with the diagnosis of prostatic hypertrophy, because he suffered with incontinence, frequency, urgency, slow stream, etc. Examination showed loss of sphincteric anal contraction with normal prostate. Further examination showed that patient also had Argyle Robinson pupils, Westphal and Romberg signs. Every surgeon must be on his guard not to operate on such a case, mistaking it for prostatic hypertrophy. In other words, he must be absolutely sure to exclude tabes. Unfortunately a number of cases of tabes have had their prostates taken out in this mistaken diagnosis.

Another case in point is a patient about 30 years old who came to the office because of frequency, loss of sexual power, pain on urination, marked cystitis, etc., with the history that he had had all the most refined technique of urologic diagnosis tried on him, such as pyelograms, cystograms, X-ray, etc., but no diagnosis was made. He has the typical loss of anal sphincteric contraction, Westphal sign and positive blood Wassermann, so that it is important to emphasize the simple examination for diagnosis as well as the more difficult ones.

Cystoscopically there are three important signs of value in diagnosing tabes. The first is relaxation of the internal sphincter, so that on viewing the sphincter through the cystoscope one finds that the waterfall is gone, that is, the inferior segment of the sphincter is relaxed, so that the bladder and urethra are one, second, marked trabeculation localized to each side of the ureteral opening, third, golf hole, or gaping ureteral mouths so that the urine does not spurt out but, so to speak, drops out.

### PYELOGRAMS

It has recently been very definitely shown that strong solutions are no longer necessary for pyelographic diagnosis. Not only have these strong solutions caused damage to the kidneys, but also edema and irritation in the bladder have resulted from solutions of sodium iodide as strong as 25 per cent. It has been shown that a 12½ per cent solution of sodium iodide gives a beautiful picture and yet causes no irritative symptoms. It is considered dangerous to take pyelograms of two kidneys at one sitting, because if there is an untoward reaction, both kidneys would be damaged at one time.

### SUMMARY

1 This paper endeavors to bring out the fact that in urologic diagnosis the history and physical examination should be gone over before cystoscopy. That cystoscopy alone is but one link in the chain and should not precede, but follow, physical examination and history.

2 In studying past history of infections, remember that the tubercular and syphilitic patients attempt to live down their past.

3 In studying chronic epididymitis think of syphilitic epididymitis and make sure to exclude it before operating for a so-called tuberculous epididymitis.

4 The so-called gonorrheal epididymo orchitis is really an epididymitis.

5 A narrow meatus may be of no significance, on the other hand, it may give a long train of symptoms by causing obstruction, back pressure and secondary infection.

6 In studying urologic tuberculosis, remember that you may have either urinary or genital or genito-urinary tuberculosis.

7 An occasional aid in urologic diagnosis is that when reaction following instrumentation is out of proportion to the instrumentation, think tuberculosis.

8 Careful inspection of any urologic case is important because by inspection one may find a narrow meatus, urethral caruncle, cystocele, rectocele, diabetic eczema, lesions on the genitals.

9 A great many so-called "neurotic urinators" in women may have pathology known as cystic degeneration of the bladder neck.

10 Cystoscopically a tubercular kidney is suspected if one has a contracted bladder plus ulceration around an ureteral opening.

11 Malignancy of the bladder cystoscopically shows a contracted bladder, profound cystitis, broad base tumor, possibly accompanied by phosphatic incrustation, plus bullous edema.

12 The cystoscope should be used in the diagnosis of hypertrophied prostate in order to know the extent, location and size of the hypertrophy and its associated complications as diverticula, stones, etc., if they be present.

broke down, urine was cloudy and at times bloody. This condition has continued till the present time. Patient looks pallid and feels weak. A sinus is found in perinaeum at the site of external urethrotomy, which is about one and a half inches long and from which cloudy urine is flowing.

**Blood Examination**—Red cells 4,020,000  
White blood cells, 11,000 Hemoglobin, 80%  
Eosinophiles, 4%

Urine slightly alkaline S G 1.026, cloudy, moderate amount of blood and pus. Microscopic examination shows abundant red blood cells, pus cells, vesical epithelium and the ova of the schistosoma hematobium.

#### TREATMENT

Intravenous injections of tartar emetic were made strictly in accordance with the method of Christopherson and in ten days the urine was clear of parasites. In a few days after the urine became negative the wound in the perinaeum began to respond to stimulation by balsam of Peru, healthy granulations appearing and in three weeks it was entirely closed.

#### CASE II

M K., Persian, age 23, occupation, carpet dealer.

**Family History**—Most indefinite.

**Previous Personal History**—Has had several tropical affections of which we have not heard of before. Thinks he had Spanish influenza about four years ago. Denies venereal history.

**Present Complaint**—Sinus over left kidney and slight hematuria. Patient states that about eight months ago he was operated on in one of our hospitals for what the doctors told him was a perinephritic abscess. Says that he drained considerable pus and urine for about two months, when wound appeared to be almost healed and he then left the hospital. In about one week after leaving the wound broke down again and has continued to discharge considerable pus and some urine ever since.

Examination shows a sinus over the left renal region, surrounded by a mass of tissue that very much suggests carcinoma (section, however, was negative), and from which pus and urine exude. Patient feels weak and has a very pasty appearance.

Examination of the urine from the bladder and from the sinus both show the presence of schistosoma hematobium.

**Blood Examination**—Red cells, 3,986,000  
Whites, 8,200 Eosinophiles, 5%

#### TREATMENT

Intravenous injections of tartar emetic were employed as in the first case, and in two weeks the parasites had disappeared. The wound, after removal of much of the excess granulation tissue, healed completely under stimulation by balsam of Peru in about eighteen days after the disappearance of the parasites.

due to the escape of the adult worms. The ova are always present in the urine, rarely though in large numbers and pyuria is present in varying degrees. On cystoscopy we find quite an interesting picture. Pedersen in his case says the picture suggested at first tuberculosis of the bladder, and at times this appearance is pronounced. The typical picture is somewhat as follows. In the vicinity of the ureteral orifice we see numerous little white ulcerations, with at times quite a yellowish tinge. These ulcers may be anywhere from a pinhead in size to that of a pea. There is usually some swelling and edema and the ureteral orifices are often difficult to locate. Bladder generally is pale and anemic, in the midst of which hemorrhagic areas appear. The trigone just to the inner side of the urethral orifice is raw, uneven and shows numerous little surface swellings, that often suggest a cystitis cystica. These are the egg pouches.

Tumor-like formations sometimes occur, in fact are said by some to be frequent. These masses usually occupy the trigone and have quite an odd color, varying from dark brown to violet. In size they vary greatly but are usually small and have the shape of a wild strawberry. French authors call them mushrooms. These tumors, produced by the irritation of the bilharzia eggs, often simulate a papilloma, and at times the so-called papillo-carcinoma. However, even real carcinoma are said to have been caused by the schistosomum. The tumors are often surrounded by granulation tissue incrustated with urinary salts, which greatly alters the picture and occasions much difficulty in the diagnosis.

Some writers tell us that they have seen the adult worm themselves waving like feathers in the bladder fluid, partly within the bladder substance and partly free. In urine containing pus and blood in quantity we at times find masses of epithelium from the kidney, pelvis and ureter, mixed with amorphous urates. In these little balls of tissue we often find the schistosoma ova, and this means involvement of the kidney or ureters as well as bladder. The deposition of the egg always produces an irritation, the ova acting as a foreign body and in the ureter it undoubtedly often causes a stricture. After operations they frequently cause the persistence of urinary sinuses, as my two cases sum quite well.

#### DIAGNOSIS

The history tells of a life spent in one of the tropical countries where the disease is endemic, or of a prolonged visit there. Symptoms of a chronic cystitis and the passage of blood usually without pain are suggestive, and absolute proof is found in the demonstration of the ova in the urine. When the eggs are found in the urine they can easily be hatched by diluting the urine about 1 to 70 or 1 to 80 with water. The surrounding temperature should be about 120° F in order to provide the necessary warmth. Under

these conditions the miracidium will be seen to assume great activity, quickly break its way out of the sack and the worm swim free in the water.

#### TREATMENT

For many years our treatment was without success, all new methods were given a thorough test and were usually found wanting. When trypanoth and salvarsan appeared we tried them both on a case without any success.

In the treatment of Christopherson our efforts are finally crowned with success and we believe it is a real specific. Christopherson injects intravenously a solution of potassium and antimony tartrate (tartar emetic), in steadily increasing doses until we are no longer able to demonstrate the presence of the parasite. The author describes his method as follows. Place a solution of the strength of half a grain to one cc. of aqua distillata in a sterile rubber-capped bottle. Begin the treatment by injecting one cc of this solution diluted with five cc of normal saline into a prominent vein. Repeat this every other day, gradually increasing the stock solution by one cc. until 5 cc of the solution (2½ grains) is given at one dose. The diluting saline should be increased gradually until the dilute mixture measures 10 cc, using a syringe of not less capacity than this. Great care must be taken to see that the needle is well in the lumen of the vein before the fluid is injected, and the patient should remain in bed for the rest of the day. Physiological effects of antimony will sometimes appear and must be watched for. In adults as much as twenty or thirty grains may be needed, in children less than half of this. In children emetin 1/10 to ¼ grain intramuscularly are sometimes found of value. Local treatments, as bladder irrigations of barley water, 5 l to the pint, or boric acid solution, are said to be of value. They are, however, not necessary, when tartar emetic can be used. Internal medication per ora, I do not believe is of any value whatever.

We report the following two cases of persistent urinary sinus as of interest.

#### CASE I

J. W., Panamanian, married, age 36, occupation, storekeeper.

*Family History*—Father died at 68 apparently of pneumonia. Mother living, has chronic malaria. One sister and brother living and well.

*Previous Personal*—Variola in childhood and yellow fever at about 16. Denies any venereal history.

*Present Condition*—States that about two years ago he began to have difficulty in voiding, his urine was cloudy and at times very bloody. Suddenly complete obstruction occurred and an external urethrotomy was performed. After the operation, wound showed no evidence of healing for six months, when an attempt was made to close it. Wound after this operation promptly

severe Many brilliant results are being obtained in this type of nephritis

The accompanying diagram is an effort to depict the factors influencing the blood chemistry, i.e., the concentration of the various chemical constituents For each substance there is a portal of entrance and of discharge The blood level depends upon (1) the intake, (2) the utilization, (3) the output The intake of all except creatinine is under the direct influence of the diet A typical disease of utilization is diabetes In this the intake of glucose is normal The tissues, however, lacking the pancreatic hormone, insulin, are unable to use it and it is left in the blood stream, the level raising until the kidney threshold is reached and we find glycosuria—nature's safety valve. Thus the fundamental factor to search for in diabetes is the body tolerance for glucose, and by regulating the intake to maintain the blood level at the proper level In nephritis the output is the site of the disease, and when symptoms point to renal involvement the problem is to determine what substance is affected and what the kidney tolerance for it is

All of the above four types of nephritis present, in the late stages, the same general picture of renal insufficiency, the whole structure being affected But the duty of the attending physician is to find out what substances are the ones affected, how badly, and from classifying it to know the natural history of that individual disease Only in this way can his prognosis and treatment be sound My purpose is to give briefly the laboratory aids in determining these factors and a summary of what we consider the normal course of each disease

As taught by Foster, nephritis may be a disturbance of the metabolism and elimination of one of three things—(1) inorganic salts, (2) nitrogenous products, (3) water The last type mentioned is diagnosed by exclusion of the other two The salt retention type is a closing of the gate on the left side of the kidneys as in the diagram and characterized by a low urinary chloride excretion, with consequent high level in the blood, and edema of the tissue due to the salt retention The termination is due to circulatory embarrassment on account of the retained fluids The blood pressure, however, is not much affected The second class, the nitrogen retention nephritis, is a shutting down of the gateways on the right, as diagramed, and is evidenced by very much increased  $N$   $P$   $N$  of the blood, retinal changes, convulsive seizures, and terminates in uremia The patient is quite anemic, with a "cafe au lait" complexion and an arteriosclerosis associated with the enlarged heart and the high blood pressure. This difficulty with the excretion of both salts and nitrogen is found in the late stages of all four types of nephritis but in the early part of the diseases it is characteristic of

the first two, i.e., diffuse glomerulo nephritis, the inflammatory type, and the primary contracted or arteriosclerotic kidney

The laboratory tells definitely which one of these we are dealing with A patient need not be in the hospital to have sufficient tests done but it goes without saying that he is under much better control if he is Even if hospitalized, the attendants should be specially instructed about the technique of the tests The most valuable single test, at the same time one that requires extreme care in the management, is the so-called Mosenthal test The patient is given a carefully measured diet containing a known amount of chlorides, usually 10 grams, with measured water intake The urine is voided every two hours during the day and the separate specimens saved and labeled From two hours after the evening meal until breakfast all urine voided is collected as one night specimen The body should be in a state of equilibrium in regard to all the constituents of the urine The total fluid intake should approximate the total 24 hour volume of urine. The chloride intake should correspond to the total output Moreover, the excretion of salt should show the following variation, namely high concentration in the samples passed after meals and a low concentration during the night. If this does not obtain, but a high chloride content is found at night, the kidneys are overworked in this regard and difficult chloride excretion is evidenced Referring to the diagram, the outpouring is fairly constant in pressure, as the level of chlorides in the blood is high The specific gravity is taken on each specimen It should show the ability of the kidneys to excrete concentrated urine after meals, and the night specimen should show that most of the solids were excreted during the day and with a resultant low gravity in the night specimen Hypostenuria or inability to concentrate the urine, as well as fixation of the gravity around one figure, are signs that mean damaged kidneys Mosenthal states that there should be a variation of at least nine points in the specific gravity, with at least one sample showing a gravity as high as 1020 The volume of each specimen is measured and in a way corresponds to the gravity At night the volume should not be over 350 cc. (the patient being instructed not to drink after the evening meal) If the body, as a reservoir, is overfilled with excretory products and fluids, the influence on the urine is easy to understand, and the kidney will work at full load for the whole 24 hrs in the day A further refinement that can be done is to estimate the nitrogen balance by calculating the amount in the food and the amount in the urine, allowing for that lost in the intestinal evacuations A standard Mosenthal diet is published in various books and articles The one we find most satisfactory is in his article on nephritis

# LABORATORY AIDS IN DIAGNOSING AND TREATING NEPHRITIS \*

By H N COOPER, M.D.,

WATERTOWN N Y

*From Department of Laboratories, House of the Good Samaritan, Watertown, N Y*

**A**S seen in a laboratory serving a general hospital, and reflecting in general the work done on various clinical conditions, kidney disease is a condition about which less critical investigation is carried on than most major body ailments. The tendency has been that if albumin and casts are present in the urine, the case is called nephritis or Bright's disease and further investigation ceases. In other words, nephritis is commonly considered to be a problem of renal insufficiency alone, of one general type and treated by a low protein, salt free diet.

The past few years have seen a great change in the solution of the factors of kidney disease. One of the results of this work has been the identification of a new nephritic entity for which the term "nephrosis" has gained great favor, this is not to be confused with hydro- and pyonephrosis. Nephritis is similar to heart disease. The damage done to the body is by cardiac insufficiency, yet no one is content to simply call the case "cardiac decompensations," but must know what is back

of this faulty action, whether a damaged valve or coronary sclerosis, fibrous myocardium, etc.

I have classed the nephropathies after Mosen-thal

1 Inflammatory changes affecting a whole or a part of the renal structure. This is the type generally called diffuse glomerulonephritis and in the late stages, a secondarily contracted kidney.

2 Arteriosclerotic kidney, also called primary contracted kidney, in which the kidney picture is a part of the general involvement of the arteries but is classed as a primary condition, i.e., arteriosclerosis localized mainly in the kidneys as it may localize in any one system.

3 Hyperpiesia or essential hypertension. This is not a primary kidney disease but due to the prolonged and intensely high blood pressure the renal blood vessels undergo sclerosis with the resulting picture of a mild primary contracted kidney.

4 Nephrosis, or degenerative changes of the tubules of the kidney, which condition may be temporary unless the toxemia which causes the cellular degeneration is too long standing or too

\* Read before the Watertown City Medical Society, February, 1925

## FACTORS IN BLOOD CHEMISTRY

a contraction of the arterioles of the whole body. It is in the nature of a spasm, as rest in bed invariably lowers the blood pressure, but it is extremely resistant to all kinds of treatment in affecting permanent results. The kidney lesions are similar to those found in the primary contracted kidneys and in fact the pathological picture is a sclerosis of the blood vessels due to the prolonged high blood pressure. The disease is characterized by a large head and no pathology there to account for the hypertrophy, a high systolic and diastolic pressure. It occurs mostly in men who lead a vigorous life and comes on at about 40-45 years of age. It is marked by frequent vascular accidents, mainly in the cerebrum, but easily demonstrated in the retina. Sooner or later, the heart decompensates. In the laboratory we find a urine with a very faint trace of albumin, occasional hyaline casts, slight polyuria, no fixation of the gravity and a normal chloride content. The blood picture shows a N P N of between 35 and 45 mgms per 100 c c. In parenthesis here, it is to be recommended that routine ophthalmological examinations be made on all cases by men who can recognize these eye changes. The first symptom of kidney trouble may be found in the retina.

The fourth type of nephritis to be discussed, is nephrosis. This form of nephritis should be greatly emphasized at this time because of the revolutionary treatment to be given these cases. Hithertofore, a patient with albuminuria and edema, is put on the time honored low protein, salt-free diet of all nephritics. As I will briefly show, this is essentially wrong and in fact a high protein diet is advisable. In outline, this disease is characterized by a gradual onset, protracted course, especially in young adults, marked edema and anasarca with effusion into the serious cavities. There is diminished output of urine, intense albuminuria, with occasional casts. The gravity may be high. No increases in blood pressure, no cardiac hypertrophy, and no nitrogen retention is found. The most characteristic finding, however, is a greatly increased cholesterol content of the blood. The reason for this lipid substance being affected is not understood but is generally attributed to the effect of the degenerated tubular epithelium. The cause for the edema in this type of nephritis is a disturbed osmotic pressure of the blood, resulting from the diminution of the protein content of the blood serum. This condition is directly due to the steady loss of large quantities of albumin in the urine. The change of osmotic pressure causes a retention of fluids in the tissues. This also explains the oliguria. The increased lipid content of the blood indicates according to Epstein, a state of impaired nutrition and constitutes an additional factor in the physio-chemical state of the blood. On this basis, he states the indications for treatment are: First, to increase the protein content of the blood and

thus restore the osmotic power. As one thinks of the enormous outpouring of albumin in the urine, combined with a low intake in the diet, the great loss of body protoplasm is evident. This still further injures the already poorly nourished tissue cells. If the urine should contain 3 per cent albumin (which is about the highest figure found and which occurs in this disease), figuring the 24 hr output at 1000 c c, there is a loss to the body of 30 grams of albumin. This figure is nearly the whole amount taken in, in a normal diet. Therefore, it is not unreasonable to increase the protein in the diet, especially as there is no evidence of retention of nitrogen in the blood. Secondly, treatment is directed toward removing the excess cholesterol which is formed from the fats. Epstein's diet consists then of a high protein content and poor in fats. Starchy foods and water are also limited. His results are remarkable. Diuresis with reduction in edema, followed very shortly after the diet was instituted. In one case, a man age 23, there was an urinary output of protein as high as 41.2 gms in 24 hrs. On the above treatment his edema disappeared completely and permanently and he was later drafted into the army. This type of nephritis occurs often in pregnancy. Careful chemical analysis of the blood is necessary before we can say that the kidneys are overloaded with nitrogen. Of course, it is well known that urea is not affected at all in eclampsia and the N P N but slightly raised. Uric acid is affected most of all, due apparently to a slight impairment of renal function. Toxemias do occur in which nitrogen retention exists but it seems probable that in most cases this is due to a true nephritis. The toxic agent in eclampsia is apparently in the rest nitrogen.

I have only scratched the surface of nephrosis but the importance of the diet and its easy recognition will stimulate further interest in these cases.

In discussing kidney tests, I have confined my remarks to only the four types mentioned. Tuberculosis, tumors, stones and other so-called surgical conditions are not included. The red test—phenolsulphophthalein kidney function test—has its most importance in these surgical cases. The selective function of the kidneys make the condition such that they are easily permeable to the dye but to nitrogen there may be distinct barrier. It is not a reliable indication of the kidneys' function as regards certain individual substances and cannot be included as a help in typing the nephropathies.

The routine examinations on a nephritic are: Routine chemical and microscopic on a 24 hr specimen of urine, a Mosenthal test, and finally that blood examination indicated in the type under suspicion. In general this means a N P N and uric acid on the early cases. If the N P N is raised a Creatinine should be per-

in "Metabolism and Endocrinology" On a carefully controlled experiment, any marked retention is easily demonstrated For example, if there is found a deficiency of three grams in urinary output, we know that for that one day alone the blood chlorides should be raised to 60 mgms, providing the tissues are as saturated as possible There are about 5 liters of blood in the average adult Three grams dissolved in 5000 c c corresponds to 60 mgms per 100 c c and with a normal blood chlorides of 450 to 500 mgms per 100 c c only a slight change is noted but the urinary picture is distinct Thus a Mosenthal test shows us exactly what the kidney is doing at the immediate time To determine the damage already done we resort to the chemistry of the blood

The salt retention type of nephritis, then, shows by the Mosenthal test a retention of chlorides, the blood chloride is raised, there is edema, no marked elevation of the blood pressure, and with the usual signs in the urine of inflammation of the kidneys

The other type of nephritis shows an early retention of nitrogen in the blood What has come to be considered a very sensitive and early sign in this type is an increase in the uric acid This substance is excreted with the most difficulty of all and is represented in the diagram as having a constricted outlet Hence, in slight renal impairment, it increases in the blood sooner than urea or non protein nitrogen This determination should then be made in early cases A rise above 2-3 mgms is abnormal The N P N represents the sum of all the nitrogenous waste products, the figure of urea being about 75 per cent of the total N P N It is composed of urea, uric acid, creatinine, creatin, amino acids and the "rest nitrogen"—unknown substances occasionally amounting to a considerable portion of the N P N Especially in convulsive uremias and eclampsias, the urea may be nearly normal, but due to the great increases in the rest nitrogen, the N P N is affected Hence, most laboratories prefer to do the N P N test rather than the urea The normal figure for N P N is 25-35 mgms per 100 c c

~ Creatinine is most easily excreted of all the products formed in the body, as is shown by a large stoma This is not affected unless very extensive damage has been done to the kidney and a rise in this means a grave prognosis is given 1-2 mgms is the usual content and when present above 5 mgms in chronic cases it signifies a fatal termination within a few months at the most.

In all types of nephritis there is, in advanced cases, a marked acidosis It is comparable to diabetic ketosis, except that it represents in diabetes an increased production of acid bodies, whereas in nephritis it is due to a diminished elimination of acid radicals, notably acid phos-

phates This is commonly the cause of death in nephritis The usual means in the diagnosis of the presence and extent of acidosis is the Van Slyke test for the  $\text{CO}_2$  combining power of the blood or plasma This test parallels the hydrogen ion concentration test, but is less subject to errors A lowering of the  $\text{CO}_2$  combining power of the plasma below 53 volumes per cent means acidosis The lower it is the worse the acidosis From 50-40 per cent there may be no clinical symptoms and here it finds its most value A case cited by Myers A boy admitted to the hospital is supposedly uremic coma, showed a remarkably low N P N, it being 44 mgms and the creatinine was 3.5 mgms, both of these being too low to account for the coma A  $\text{CO}_2$  combining power of 22 volumes per cent showed the difficulty After giving two infusions of bicarbonate of soda, remarkable clinical results obtained, and in less than two weeks the blood chemistry was normal

A word of warning, however, in regard to the indiscriminate use of soda bicarbonate is needed While acidosis is a dangerous condition, over-feeding with bicarbonate results in alkalosis, which also may terminate fatally Alkalosis is present if the  $\text{CO}_2$  combining power of the plasma is over 77 vol per cent An illustrative case, though not a nephritis, is reported by Myers and Killian Following a cholecystectomy  $\text{NaHCO}_3$  was given by rectum for 24 hours A study of the blood chemistry at that time showed a urea N of 29, sugar 262, and  $\text{CO}_2$  of 95 vol per cent There were spasms of the facial muscles and other evidences of tetany, coma, pulmonary edema and death Tetany is one of the chief symptoms of alkalosis In a recent article by McVicar of Mayo clinic, he emphasizes the study of the blood chemistry in intestinal obstruction and states that all these cases show a tendency toward alkalosis and that bicarbonate in treatment is contra-indicated Benefit comes from giving salt, sugar and fluids He definitely states that tetany may be expected whenever the plasma  $\text{CO}_2$  goes above 100 vol per cent, and that it is a complication of this form of toxemia At present, data indicates that large doses of bicarbonate should not be administered without knowledge of the plasma  $\text{CO}_2$  Normally 5-10 grams of soda will render the reaction of the urine alkaline, but in acidosis 100 grams may be needed The method of giving soda until the urine is alkaline is not without danger, as excessive doses are required

Alkalosis and acidosis are illustrations that, following a study of the blood chemistry, rational treatment is indicated and without which one works in the dark

Hyperpiesia, the third main grouping of nephritic conditions, is primarily a disease of the circulatory system in which some stimulus causes

at the De Milt Dispensary. In 1882, the New York Post-Graduate School and the Polyclinic began their work as friendly rivals, while the great undergraduate schools showed them active opposition. Two factors which have contributed to the success of your school have been (1) that of forming a clinical center, instead of there being a necessity for the student to waste his time in going from one hospital or dispensary to another, separated by great distances, and (2) the policy of having the control of the institution and the teaching in the hands of successful clinicians.

Those connected with this institution in its early days agree that to Doctor St. John Roosa should go the chief credit for its success. It is true that Doctor W. A. Hammond, Surgeon General of the Army during the Civil War, and a man of extraordinary vision, was the moving spirit in planning the school, but it was Roosa who carried out those plans in the face of great difficulties and much opposition.

In his address delivered at the inauguration of the New York Post Graduate School, November 11, 1882, Roosa established principles for the conduct of such a school which hold today as well as they did 40 years ago. To give you an idea of the excellence of his views I have made a few notes from this address.

"Our object is not to make more doctors, but to improve those we have. We propose to make a center in which it will be possible for a graduate in medicine to fit himself for the detection and treatment of the diseases that are not fully discussed in the studies and lectures of an ordinary course in a New York Medical College.

"Many practitioners come to New York every year to acquire the practical knowledge of diseases called special, but which they find to be very general.

"It would be easy to show that Berlin and Vienna have acquired their prominence as medical centers not by teaching of undergraduates, but by the instruction furnished to medical men.

"Circumstances over which we have no control have compelled us to add another unendowed school of medicine to those that now exist, but we have no idea that it will remain so. When we have demonstrated our usefulness and the necessity, we shall seek an endowment at the hands of our fellow citizens. We believe that the governing bodies of our universities will yet make them so in fact as well as name, that medical colleges will become an actual part of them and that then the post-graduate medical school will have its appropriate place. Not division, not separation, but unity in university instruction is what we seek and what we believe our institution will ultimately promote.

"Paris, Berlin, and Vienna have obtained their enormous power over medical action and thought, in part at least, because the faculties of their

great universities have comprehended nearly all the men in the cities who have been competent and willing to teach medicine. There has been concentration of effort at one center. That consummation I earnestly hope for New York."

This address shows that Roosa had in mind the providing of courses to supplement deficiencies of the undergraduate training or rather to make better doctors. Some of you may think that such views may have been true 40 years ago, but no longer holding today. If you will read the articles which have been written recently, on the imperfections of our present undergraduate medical training, you will be convinced that we have the same need today of post-graduate clinical training that existed at the time of Doctor Roosa's address. There is no lack of criticism in the following remarks by Cushing.

"However, we will, almost all of us, freely admit that probably nine out of ten students enter medicine with the expectation of engaging in practice and it behooves us, therefore, to give them the best possible training for this responsible career. Whether we are doing so at present is open to grave doubts."

The steady increase in extreme specialization in the pre-clinical years, along with little or no correlation between the basic science departments, has produced a state of bewilderment in the student. Unfortunately, these scientific subjects have progressively become wider in scope and more difficult, so that the clinical teacher who pursued these studies 20 or 30 years ago is not in a position to answer the questions of the groping student as to the proper relation of such studies to the real problems of diagnosis and treatment.

We must all agree with Louis B. Wilson in his statement that the attempt to teach six complete medical sciences in the first two years of the medical course, any one of which would require the full attention of the student during this period, is responsible for the superficial knowledge on the part of the recent graduate of the essentials and unessentials of anatomy, biochemistry, physiology, pathology, bacteriology and pharmacology. This, in his opinion, accounts for the inability of the present day graduate to apply the essential principles of the pre-clinical branches to the study of his cases. Again, he states that the physician who has a sufficiently thorough knowledge of the essentials of the fundamental medical sciences to use them as familiar tools in the every-day study of complicated individual cases, is unfortunately getting rarer, and his production is not favored by the present cramming system in our medical schools.

It is my belief that Pepper has instituted a plan which offers great promise in the correction of this serious defect in medical education. Briefly this plan is in the holding of one clinic each week for the members of the two lower classes, in

formed. A blood chloride on cases with edema and when indicated by the Mosenthal. The chlosterol is indicated in cases with edema with marked albuminuria, and a  $\text{CO}_2$  combining power of the plasma in all cases that are acutely or desperately sick.

In conclusion, the help in investigating these conditions depends upon the individual physician and the particular laboratory. Laboratories, when properly supervised, are now considered not merely a technical shop but a real consultant in

medicine, a specialty all its own and for which as careful training is necessary as other specialties. Some diseases are surgical in nature, others neurological, and so on, while some are pre-eminently laboratory diseases. It is not expected that the general practitioner will know all the technical details, but the plea is offered that the laboratory will be consulted, personally as well as by submitting samples, as this is the only way the full benefits can be obtained. To do justice to the patient is the duty of every physician.

## UNDERGRADUATE DEFICIENCIES AND POSTGRADUATE REQUIREMENTS

By E R STITT, M D REAR ADMIRAL, U S N

IN his "Oath" Hippocrates has given us a professional standard which has held as the ideal of the relations of the physician to himself and his fellow man for almost twenty-five centuries. In his "Law" we have a statement of the essentials for the making of a physician which put beside all our writings on this subject, in this present day, easily takes first rank. In this "Law" we learn that who ever is to acquire a competent knowledge of medicine should first of all have a natural talent, for when Nature leads the way to what is most excellent, instruction in the art takes place, which the student must try to appropriate to himself by reflection, becoming an early pupil in a place well adapted for instruction. He must also bring to the task perseverance and a love of labor. Instruction in medicine is like the culture of the products of the earth. For our natural disposition is, as it were, the soil, the tenets of our teachers are, as it were, the seed, instruction in youth is like the planting of the seed in the ground at the proper season, diligent study is like the cultivation of the fields and it is *time* which imparts strength to all things and brings them to maturity. From this we shall see that Hippocrates clearly valued the early training on the part of our teachers as only the seed in the ground, which would spring from the soil following diligent study but that it was time alone which would give rise to the true physician. Again he tells us that certain persons have the shape and dress and personal appearance of the actor, but are not actors, so also physicians are many in title, but few in reality.

Shall this time which is necessary to make us real physicians be solely a period of individual practice, gaining experience tediously and uncertainly, often through error or failure, or shall we intersperse our professional lives with occa-

sional clinical courses obtained in one of several ways.

This opportunity can best and most expeditiously be gained through some plan of post-graduate training and this, in my opinion, is satisfactorily provided along the lines of the New York Post-Graduate Medical School and Hospital.

Such a school should be located in a great seaport, because shipping brings in a great variety of cases, which sharpen the wits of the hospital staff. Then, too, as the greatest and wealthiest city of America, New York attracts the best medical talent, whose services then become available for clinical teaching. In this great body of medical men are many capable young general practitioners whose services as instructors in the out-patient departments would be of the greatest help to the graduate students.

In your school you have a wonderful mass of clinical material in your dispensary service, capable of great expansion. Mackenzie insists that the general practitioner is the only man suitably placed to elucidate the problems of the commencement of diseases and their progress towards their eventual termination. Hence he argues that the general practitioner should take a more active and prominent part in teaching.

In the hospital you have beds to receive cases transferred from the dispensary, so that the student may follow up such patients in the wards, where are provided facilities for scientific observation and research. Among the essentials for a post-graduate medical school the House of Delegates of the American Medical Association stressed the availability of ample clinical material, to afford the student in the general practitioner courses opportunity personally to examine patients in the out-patient departments, as well as in the hospital wards, including facilities for laboratory examinations. Apparently post-graduate work along the lines of that then existing in Europe was first taken up in America in 1875,

\* Address at the dedication of the James McKernan Building of the Post Graduate Medical School and Hospital January 22, 1925.

conjunction with the medical seminar, served as the basic training

Very important for these men were the courses in neurology and psychiatry. With an inexpensive diagnostic set, a microscope and sufficient equipment for making simple urine and blood examinations, I am convinced that these physical examination specialists will be able to pass on physical deficiencies without having to call in the services of a group of specialists except in rare instances.

Considering the present widespread interest in annual physical examinations, and the recognized shortcomings of the average general practitioner to conduct such examinations, would not such a training be desirable and practicable for University medical extension courses?

Would it not be well for the New York Post-Graduate School, with its body of enthusiastic young teachers, to take part in this movement? You may question my excluding the older teachers, but I have done so advisedly, because the missionary work of going from small town to small town, and even villages, covering many miles of travel each day, for six or eight weeks, is a young man's game and requires a young man's enthusiasm.

I doubt not but that many of you are wondering at the omission of any reference to post-graduate instruction for the making of specialists. We know that some of our Universities are devoting most of their postgraduate medical efforts to the elaboration of two and three-year courses, planned to produce a fully equipped specialist. In England, they do not look with favor on such methods for training specialists, but prefer that the well-trained general practitioner, who may aspire to spe-

cialism, attain his qualifications by holding junior appointments, such as clinical assistant.

Again, taking counsel with Hippocrates, we believe that a general practitioner should have a natural talent for the specialty he proposes to cultivate. We know that many a poor ophthalmologist might have made a successful psychiatrist, or a failure as a surgeon a success as a sanitarian.

I am firm in the belief that no one should enter upon a specialty until he has had a few years of general practice, not only that he himself may know that he has aptitude for the specialty he has in mind, but that his colleagues may be of the same opinion, and recognize in him the man they would choose to call in consultation. I think it is well for a postgraduate medical school to have courses in the specialties, but these should be for the making of the best type of general practitioner, and it may be that some of the present generation can at length follow in the footsteps of Johnathan Hutchinson, a multi, or super-specialist. Let the specialist come up from the ranks of the general practitioner, surely and slowly demonstrating his fitness for specialism, and then receiving the stamp of qualification through graded service in a special clinic. This point of view is forcefully expressed by that leader of English medical thought, Clifford Allbutt, in the following paragraph:

"If one qualifies as a specialist by falling into ignorance of all else, his pretension is vain, if he is to look his problem fully and intelligently in the face, he must take up the all else into that special study. The harm of specialism lies not in a limited field but because the specialism is reached by not carrying the whole into the part."

## BREAST FEEDING

By FRANK HOWARD RICHARDSON, M D,

Chairman of the Post Graduate Education Committee of the Brooklyn Pediatric Society

BROOKLYN NEW YORK

Abstract of the first Clinical Lecture in a course on Practical Pediatrics given in the Southside Hospital, Bay Shore N Y, under the auspices of the Suffolk County Medical Society

My subject is "Simplified Infant Feeding and the Breast." Modern infant feeding can be immensely simplified. Its elements are first, breast feeding, and second, complementary feedings of cow's milk, if necessary.

The preparation of artificial foods has also been greatly simplified, and consists of two essentials: first, the modification of the milk with water and sugar only, and second, boiling the milk.

My lecture will consist principally of the elaboration of these principles.

Feeding a baby on commercial artificial foods is not the easy process that many people think

The formulas are complicated, and have a basis of cow's milk, and the preparation of the foods is troublesome and time-consuming. It is a much simpler process to put the baby on the breast, and give it complementary feedings if necessary.

Most of the work on simplified feeding has been done in private practice. The hospitals have done little accurate work in that line because well babies seldom go to the hospital, or stay there long enough for accurate studies.

Ninety-six per cent of all women can nurse their babies to some extent if they will go at it in the right way. They may not be able to pro-

which the practical application of anatomy, physiology and physiological chemistry is correlated with the subjects studied during that week. I have learned from Professor Pepper that this correlation has meant exacting study, on his part, to keep abreast of the current class work in the fundamental sciences.

This plan involves such effort on the part of the clinical teacher many years removed from his fundamental sciences, that I doubt whether it will become generally adopted.

Would it not be possible for such an institution as the New York Post-Graduate College to have a course in internal medicine in which the clinical side of the cases could be presented by the senior professors, and the correlation of the fundamental sciences presented by junior teachers in whose minds the essentials of anatomy, physiology and other basic medical sciences are still fresh?

In such a course an effort should be made to demonstrate the possibility of making diagnoses in a large proportion of cases by the methods used by the great clinicians of 5 years ago. I do not mean to belittle the advantages of blood chemistry, electrocardiography and the like, but I do believe such aids have their place more in confirming than in making diagnoses. Some of our recent graduates would feel themselves helpless in an ill-equipped, small-town hospital, not so much from the lack of the various modern laboratories as from the lack of a staff of specialists capable of performing and interpreting laboratory tests. In other words, there is too much dependence on others to make our diagnoses.

Allow me to quote from an article by Sir George Makins, in which he says:

"The habitual resort to special methods, and the belief that complicated apparatus is necessary in the investigation of the ordinary problems of disease, is likely to do as much toward the destruction of the art of the practitioner as the methods of science can do to help it."

In our worship of the science of medicine we bid fair to lose that art of medicine which gave the old family doctor such a hold on the people of a former generation. I would even recommend a postgraduate school to give courses in practical nursing, a lost art for the physician, and one which stands in danger of disappearing in the tendency to substitute science for art in the modern training of nurses.

There is too much made of theory and basic principles and too little of practice and observation.

I believe that the majority of clinical teachers will agree with Capen's statement that the natural and instinctive action of the human mind is to proceed from practice to theory,

from the concrete to the abstract, and that to give theory first and practice last is a pedagogical sin. Theory should be illuminated by practice.

The physician should be trained to observe and investigate. We should give thought to President Burton's views that the art of the practice of medicine would seem to be identical with the art of investigation, for investigation is also an art, and the educational approach to the training of the investigator and the physician appear identical.

The earnest physician should make it his endeavor to refresh his knowledge by taking post graduate courses every two or three years. There is now so much to be learned in our own schools and clinics that many students do not think it necessary to go abroad for further training. I believe we should first avail ourselves of the post-graduate opportunities now offered at home, but it would be wise to intersperse this periodic professional refreshment with attendance on European clinics. Flexner was right when he recently said that however much we have improved we are not good enough to be sufficient unto ourselves, and we never shall be. Science is international, it advances in most unexpected fashion, now here, now there. And stimulus does not communicate itself best through the printed page. Men must know one another and work with one another.

The plan we have been outlining of having medical men come to a medical centre for post-graduate instruction is manifestly the desirable one, but many of our country practitioners, eager for professional improvement and greatly needing such opportunities, cannot for various reasons absent themselves from their homes. To meet such demands there is now developing a program of University extension for medical teaching.

Where a hospital has been available, as a center to conduct clinics, the success of the movement has been unquestioned, and even when such clinics have been conducted in towns without hospitals, the value of the training has been attested by the country physicians, enrolling in such courses. Naturally, outside of hospitals, only courses in such subjects as pediatrics, physical diagnosis and pathology are practicable. During the past year I have had two of our medical officers take up special training to fit them to conduct our annual physical examinations and to pass on the physical qualifications of recruits. It may interest you to know that I selected the New York Post-Graduate School as the institution offering the training best adapted to this purpose. The diagnostic clinic, taken in

to use in place of a suppository. It consists of a pencil of soap three or four inches long with its upper end enlarged to serve as a handle. The advantage of the soap stick is that the mother can see it and can hold it in the rectum, and can use it over and over.

How should we empty a breast?

Not with a breast pump. The breast pump does not imitate the act of sucking. It fails to withdraw the milk, and it does not stimulate the production of more milk.

Not by massaging the whole breast. Massage does violence to the breast, and is not a proper procedure even when the breasts are enlarged and hard.

The proper way to empty a breast is to "milk" it as a dairyman draws milk from a cow. A study of a diagram of the milk ducts will indicate the rational method of withdrawing milk from them.

The outlet tubes of the milk glands converge toward the nipple, and end in reservoirs, which open upon the surface of the nipple.

How shall we draw milk from a woman's breast? The two photographs show the process. The first act consist in grasping the breast, just back of the areola, between the thumb and forefinger.

FIG. 1—Grasping the Areola.

The second act consists of closing the thumb and finger upon the breast tissue, and drawing them forward. The fingers do not slip over the skin, but they draw the whole grasped part forward.

About five minutes time will usually be sufficient for emptying a breast by this method. The mother can easily learn to do it. Teach her to use the right hand for her left breast, and vice-versa.

It is impossible to draw a breast so dry that not a single drop of milk will be obtained. The breast continues to secrete milk while the milk is being drawn.

Practically every woman who has had a baby of nursing age will have some milk in her breast for weeks or months after weaning. This may readily be drawn in drops. Drawing the milk regularly every three or four hours will stimulate the breasts to produce an increased quantity which in two or three weeks will be sufficient for the needs of a baby. This is not a mere theory, it works.

At first the milk may come in drops, but after a few days a spurting stream may be obtained. The demonstration of a spurting stream has a tremendous psychological effect on the mother and her relatives.

FIG. 2—Compressing the Breast Tissue.

#### DRAWING MILK FROM THE BREAST

It must not be supposed that emptying the breast is the only procedure that is necessary in order to produce an abundant flow of milk. Equally important is it that a woman should avoid getting tired, either physically or mentally. Fatigue is the greatest enemy of a full flow of milk. Dairymen all know that.

Food has little or no effect on the production of milk, it only it is abundant.

Now a word as to complementary feedings. The materials consist of cow's milk, water, and sugar.

The milk to be used is the best quality of milk

obtainable. It may be well to remove some of the cream if the milk is unusually rich.

The amount of water to be added to the milk is equal to the amount of the milk. It is seldom necessary to make the feeding more than half water, and only a quarter water is the more usual proportion. The principal use of the water is to supply the amount of water that the baby needs.

The sugar may be dextre-maltose, milk sugar, or plain cane sugar. The amount is usually one ounce to each quart of the mixture, increased to 1½ ounces per quart as the baby gets older. Don't use so much sugar that the milk tastes sweet and leads the baby to refuse the breast.

vide all the milk that a baby requires, but even a small proportion of breast milk is sufficient to provide the special vitamins and other elements which tend to make breast-fed babies more healthy and vigorous than those which are entirely artificially fed

Breast milk will practically always agree with a baby. The notion of its often disagreeing comes from the common observation that a baby often cries and kicks with so-called "colic" after it is nursed. Colic means hunger in ninety-nine per cent of all cases, and will be cured by additional food given as a complementary feeding.

It is a common belief that menstruation impairs the quality of breast milk. It can do so only by inducing a loss of water, and undue fatigue.

The modern standard of baby feeding is to give the child all the breast milk that the mother can produce, and then to give him all the artificial food he wants. A standard rule is to place the baby on the breast for twenty minutes, and let it get as much breast milk as it can, and then immediately give it as much artificial food as it wants. But be sure to start the feeding with breast nursing.

Suppose a mother has little or no milk, or loses her milk, what can be done then?

The production of breast milk can be stimulated rapidly and surely by an extremely simple procedure which every dairyman knows all about.

A sure way to *stop* the production of milk—that is, to dry up a milk producing animal—is to stop drawing the milk. Failure to empty the breast completely is almost as bad as not emptying it at all. Every dairyman knows the necessity of stripping the last drops of milk at milking time. The first essential in promoting the flow of milk is to empty the breasts completely at each nursing.

Dairymen also recognize the extreme importance of regularity of milking time. The production of milk will fall off if the animal is milked at five o'clock on one day and nine o'clock on another, according to the convenience of the farmer. Regularity of nursing is equally important to mothers.

It is not desirable that a mother should burden herself by nursing her child every two hours. If the baby wakes up and demands food within two hours after a nursing, the child has probably got too little food, and the clear indication is for a larger amount of complementary feeding.

A mother can put her child on a four-hour interval of feeding, and she can even skip a nursing and give the child one feeding of the artificial food, provided the feeding times are regularly spaced and maintained. Eight hours freedom from nursing on occasion when necessary is enough to enable any woman to attend to her social duties.

It is not necessary to use both breasts at every

feeding. Use one breast at a feeding and the other breast at the next feeding.

How long should a baby nurse? About two-thirds of the amount in the breast will be drawn during the first five minutes. There is usually nothing to be gained by continuing the nursing beyond twenty minutes, though it may occasionally be desirable. A good rule is to nurse the baby twenty minutes, and then spend five minutes in drawing the remaining milk by hand.

Emptying a breast completely at each nursing is necessary in maintaining or promoting the flow of milk. Emptying the breast is the only practical stimulant to the production of milk—and it is an efficient stimulant. Cases are known in which the stimulation of nursing virgin women has caused the regular production of a full flow of milk.

If a baby is hungry, why does it fail to draw all the milk from the breast? We don't know why some babies are lazy and simply will not nurse. Others will stop their efforts if only a small amount of milk flows, or the milk comes slowly.

We must accept the fact that many babies often fail to empty the breast, and therefore the artificial emptying of the breast is necessary. However, there are two conditions which often prevent babies from nursing—first, air in the stomach, and second, a full rectum.

A considerable amount of air in the stomach is a natural condition in young babies. Milk will not run into a stomach that is full of air, any more than it will run into a narrow-mouthed jug that contains air, but remove the air and the milk will flow into the stomach readily.

The application of this principle is plain. A baby may start to nurse, but in a few minutes be satisfied because the food plus the air fills the stomach. But in a quarter or half an hour it wakes up crying and kicking, and when the mother takes it up and pats it a lot of air is belched up, and the "colic" (which was hunger) stops, and the child takes a normal amount of food.

If a child does not nurse well, air in its stomach is the first cause to be considered. The means of diagnosis, and the treatment, consists in the mother's holding the baby over her shoulder, thus expelling the air. The baby will then nurse normally. It is well for a mother to use this as a routine procedure during every nursing.

A full rectum, and gas confined in the stomach, may also prevent a baby from nursing. If a baby does not nurse after the removal of gas from its stomach, give it a soap suppository in order to make its bowels move. The expulsion of feces and gas will often be followed by normal nursing.

A soap stick is a simple device which is handy

## TUBERCULOSIS DAY

The X-ray demonstration alone will be worth a day's time of any practicing physician. Commercial firms will demonstrate the recent improvement in X-ray machines and trained roentgenologists will demonstrate the uses that may be made of the machine and how to secure the best results. Dr. Lloyd and associates from the Monroe County Tuberculosis Sanatorium will bring with them a variety of radiographs which they will explain individually to any physician who will visit with them long enough.

Dr. Amberson, of Loomis Sanatorium, will have on exposition several series of radiographs showing the progress of recovery from the time the patients entered the Sanatorium until dis-

charged, and several radiographs made months subsequent to discharge.

Dr. Bela Schick will exhibit several series of radiographs made on infants from a year to three years of age, which show admirably how in the early stages of children so young the disease is less clearly defined than in later years.

Dr. Henry D. Chadwick, of Westfield Sanatorium, Massachusetts, will exhibit several series of radiographs taken from children between the ages of seven and seventeen, in whom no definite clinical symptoms of tuberculosis could be found save history of loss of weight or anemia. The radiographs show definite enlargement of the lymphatic glands in the vicinity of the hilum

It is now the custom to boil the milk which is fed to babies

First, boil the water which is to be used  
Second, add the cold milk to the boiling water, bring the mixture to a boil, and continue the boiling for three minutes

Third, add the sugar

Fourth, let the mixture cool, and keep it in a cool place

This simple procedure is about all there is in the modern preparation of artificial food for infants

Boiling the milk need not arouse a fear of scurvy, especially if the baby also gets some breast milk. But any possibility of a deficiency disease is prevented by giving orange juice. Start with a teaspoonful once a day when a baby is two or three months old, and increase it up to the juice of half an orange

Thirty drops of cod liver oil twice daily, increased later to a teaspoonful, is an insurance against rickets. It is readily taken and never does harm

As to the amount of artificial food to be given after a breast feeding—give the baby as much as it wants. Some babies will vomit or rather regurgitate some of the milk. This may be curdled, as milk should naturally be after it has lain in the stomach a short time

Some babies will pass curds in their stools, and remain perfectly well. These babies seem to have an active peristalsis, which hurries the milk down the intestine before it is fully digested

Green stools often alarm both the mother and the doctor. A green stool in itself is no cause for worry

Mothers run into all sorts of difficulties in

feeding their babies, and they appreciate the supervision of a physician who is really interested in well babies and in keeping them well. Mothers must be educated in regard to bringing their well babies to their doctors. It is the doctor's duty to offer his services to his mothers, and then to give them actual service according to modern pediatric standards. A physician is perfectly ethical in offering service to the well babies of his families

It is more satisfactory for the doctor to have the mothers bring their babies to his office, rather than for him to go to the mother's house.

A doctor needs scales for weighing the babies. It is good psychology for a doctor to provide the visible means for practicing pediatrics. Excellent scales may be bought for less than fifteen dollars. A desirable kind is one that can be carried in a suit case to the homes of the patients, if necessary

We will now show this case. She is a healthy, well-nourished woman who gave birth to a healthy child three weeks ago, but she has "lost her milk," from no apparent cause

We find that the breasts and nipples are well formed, and normal. As we express the milk in the way we have just discussed, we obtain a drop or two at each act of expression. You will note that the patient herself is able to draw the milk, and that she says she is anxious to "bring her milk back"

She will express the milk for five minutes every three hours during the day, after inducing the baby to nurse as much as it will

We will ask the patient to return in two weeks, and we expect that she will then have a good flow of rich milk

## Deaths

BENNETT, FRANCIS J. A., Auburn, University of Michigan, 1911, Fellow American Medical Association, Member State Society, Orthopedic Surgeon, City and Mercy Hospitals. Died February 9, 1925

BOWERS, JOSEPH HENRY, Albany, Albany Medical College, 1912, Fellow American Medical Association, Member State Society, Attending Obstetrician St. Peter's Hospital. Died March 30, 1925

KAUFMANN, WILLIAM PEROT, Haverstraw, University of Toronto, 1906, Fellow American Medical Association, Member State Society, Visiting Physician Good Samaritan Hospital. Died April 3, 1925

LYON, JONATHAN FISH, New York City, Heidelberg 1880, Fellow American Medical Association, Member State Society. Died April 9, 1925

MERRITT, FREDERICK CHARLES, Sayville, Trinity, Toronto Canada, 1891, Fellow American Medical Association,

Member State Society, Physician South Side Hospital, Bay Shore. Died April 7, 1925

MILLER, AARON B., Syracuse, University of Maryland, 1882, Fellow American Medical Association, American College of Surgeons, American Obstetrical & Gynecological Society, Member State Society, Consulting Gynecologist Memorial & Free Dispensary, Gynecologist St. Joseph Hospital. Died March 28, 1925

SWAIN, FRANK S., Corning, Ohio Medical College, 1903, Fellow American Medical Association, Member State Society, Surgeon Corning Hospital. Died March 7, 1925

ZABRISKIE, WILLIAM H., Glen Cove, College of Physicians and Surgeons of New York, 1885, Fellow American Medical Association, Member State Society, Surgeon Nassau Hospital. Died March 31, 1925

learners, for they are illustrated by actual cases which the students bring

The ideal outfit for giving postgraduate instruction in the practice of medicine consists of three elements

1 A hospital to supply cases for study and the facilities for their observation and treatment

2 A group of learners—the doctors on the hospital staff

3 A leader—a doctor who has had a little wider experience than the members on the staff

To bring together these three elements is the fundamental conception of the Joint Committee on Graduate Education of the Medical Society of

the County of Kings and the Long Island College Hospital Medical School The novel feature of the Kings County plan of graduate education is that it permits physicians to attend classes without loss of time from their practice Much of the instruction is given after four o'clock—between office hours and supper If the classes cannot come to the teacher, the teachers come to the classes

This plan of graduate medical education is no mere theory It is entirely practical, as is shown by its successful operation in Brooklyn, and its extension into Suffolk County

### TEACHING CLINICS

We believe that one of the functions of the Medical Society of the State of New York is to raise the standard of the art and science of medicine among the great mass of its members While the members wish to be informed regarding the latest developments of the surgery of the heart valves, a subject of infinitely more general value is that of the management of the heart patient

It is certainly the function of this Journal to print educational articles of a medical nature The Editor is necessarily somewhat of a pedagogue who lays out reading courses to the members of the State Society Some of the courses which he prepares do not interest certain groups, and other courses seem to be either too elementary or ultra scientific

We believe there is a field for simple articles on elementary topics, such as breast feeding We all know how few details of breast feeding are taught to medical students,—there is not time enough to begin to cover them all

Then, too, the medical school deals with medical topics impersonally,—a doctor in private practice usually deals with a patient primarily, and with a disease only secondarily

We believe there is a large field for simple articles that are almost text book in their nature, on practical every-day topics Does a doctor know, for example, the fundamental principles of modern breast feeding? Let him turn to page 653 of this Journal and read the abstract of an actual clinical lecture on breast feeding given to a class of twenty average physicians who were so impressed with the practical suggestions of the lecture that they at once agreed to meet weekly for more lectures

We would like to secure one or two similar articles on other topics for each issue We think that "office orthopedics," for example, will make an excellent subject for elementary articles on the cure of feet which ache and are sore

We also venture to suggest that the State Medical Society could readily promote teaching clinics as parts of the programs of country medical societies We know, for example, that the members of the Staff of the University of Syracuse are ready to supply clinical demonstrators to go on the program of any medical society in their vicinity The Medical Societies of Suffolk and Nassau counties are adopting the clinics Why don't other counties do the same? ### THE NURSE REGISTRY

In the golden age of long ago hallowed by legend and nebulous in memory the nurse caring for the sick was an outstanding community character known by everybody and sought by everyone in need of nursing care Today in the State of New York alone there is an army of thirty to forty thousand men and women who obtain a livelihood by attendance on the sick or from allied activities Today one seeking the services of one of this host of nurses rarely has acquaintance with or even knowledge of the particular individual who responds to the call The want is supplied through bureaus or agencies quite similar

in character to those employment agencies which supply labor on demand These bureaus, technically Nurse Registries, in number are many They are differentiated by several terms, those conducted by training schools only register their own graduates, those managed by nursing organizations only register nurses who have similar credentials to the members of the organization, those operated in any other way register all applicants whatever their training or experience and they are called "commercial registries"

According to the quantity and quality of the preparation for nursing service these thou-

In several of the series portions of the lungs were involved. He gives a very satisfactory explanation of the progress of the disease as due to the destruction of a gland discharging into a neighboring bronchus. In none of such cases was the apex involved, thus confirming his diagnosis.

It is hoped that Dr. Cole will find it convenient, between eleven and twelve o'clock on Thursday, to present his moving picture on construction and interpretation of radiographs.

If any physician is having trouble with his X-ray machine in securing satisfactory radiographs or if he has radiographs difficult to diag-

nose, it is suggested that he seek advice and aid of any of the men in charge of the exhibits. No question will be considered too elemental or simple to be discussed and answered by those in charge. It will aid them to make their contributions more valuable to have subjects brought to them for discussion.

For the interest of those who may have no special questions, there will be given in the afternoon a short talk by one of the roentgenologists on the technique of taking a radiograph and interpreting it. (Program, p. 669) J. S. L.

## MEDICAL SURVEYS

The medical surveys which we began early last summer were an outgrowth of our reportorial attempts as we visited a few medical centers seeking news and suggestions for the Journal. We found that the physicians in every community were doing some one or two things exceedingly well, and in a way that was worthy of publicity. We also found that the doctors of a community seldom could give accurate information regarding medicine in their own county, or city, and much less regarding it in other parts of the State.

We were gratified with the absence of sectionalism. Physicians have a fraternalism which gives them a kindly feeling for their confreres throughout the State.

We have just made a medical survey of Greater New York. It is necessarily superficial and sketchy,—as are all such surveys of the city, whether they are made by individuals or endowed corporations.

If we survey impersonally, we can draw all manner of conclusions. We can decide that the physicians of Greater New York are self-satisfied, and know little about medicine in other parts of the State. Or we can point to the marvellous

achievements in surgery and research, and the immense hospitals and medical schools, and can conclude that with all these advantages the physicians of New York City must be super-doctors. And we will be equally right and wrong, as are most other investigators.

We tried to approach our survey from a *personal* point of view. The great city has several thousand physicians with the same training and inspirations as their up-state confreres. They are confronted with problems that are their own, and belong to no one else. The physicians in each section have solved their own problems in their own particular way. It happens that the methods of solution adopted by the Manhattan physicians, differ fundamentally from those developed in Brooklyn, but who shall say which is the better? Each is best for its own community.

But in one respect we have found entire unanimity among the doctors of both Greater New York and the rest of the State. They are entirely fraternal, cooperative, earnest, and sincere, and all are earnestly trying to solve the problems which are within the scope of the Medical Society of the State of New York.

F. O.

## THE PRINCIPLES OF GRADUATE MEDICAL EDUCATION

We are now at the cross roads in medical education. The training of physicians in medical schools is both a science and an art. The medical schools can teach medical science, but they cannot teach the art of practicing medicine.

What is skill? It consists of information, experience, subconscious memories, wisdom, and action. It can be transmitted from one individual to another provided the recipient has both inspiration and desire.

A physician is like a school child who is satisfied to be like the others in his own group. A school boy who is in a class with more advanced pupils will study hard in order to keep up with his superiors. In a group of medical equals there

is no one to show the others better methods of diagnosis and treatment, but a group with a leader is a learning group.

The hospital where all the physicians of a community come together offers the means whereby a physician can learn the art of the practice of medicine. It can take the place of the preceptor of former days when the younger men learned from those who were more experienced.

The hospital is a place of learning in distinction from teaching. It is a place where the members of the staff confer with the consultant as his social equal. It is a voluntary association, and the subjects of discussion are chosen by the

## SHOULD NOT THE PROFESSION DISCOURAGE BASELESS MALPRACTICE SUITS?

As the Annual Meeting of the House of Delegates approaches, we pause to look back upon the past year to give an account of our stewardship in this department.

We find that active as we have been in the disposition of suits brought against doctors, we have been unable to keep pace with the influx of new suits, that although we disposed of ninety-nine cases, we received one hundred and eighty-one, and that our calendar of pending lawsuits against physicians is now two hundred and eighty-four.

Of the ninety-nine cases that we have disposed of, seven were settled, ninety-two were won, and none were lost. These figures indicate that 7 per cent of the cases disposed of had merit on the plaintiffs' side and if we adopt this ratio for pending cases it would indicate that of the two hundred and eighty-four cases pending, about twenty are based upon actual liability.

It is not the case of actual liability that really gives trouble, because the damage that has been done can be assessed and paid for under our present system of group insurance. This system is but right to the doctor and fair to the patient. The cases which in fact are not based upon actual liability, give the most anxiety, for we realize that by one method or another the plaintiff will seek to bring forward such testimony as will create a legal liability and result in an assessment of damages against the physician, whether that judgment be just or not. To defeat these efforts occupies a great deal of our attention and is cause for considerable of our anxiety. In practically every such cause there is something—usually in the result of the doctor's treatment—that makes the patient believe that he has a just grievance. There is some excuse for this attitude on the part of the layman, but there is also in such cases, hidden away somewhere, some doctor who, either by injudicious criticism or from motives less worthy, is responsible for inciting the plaintiff to start his action. In the last analysis it is this type

of doctor upon whom the responsibility for many such suits rests. In at least one instance that could be proved by the record. A young doctor in a community was dragged through days of anxious trial because another and older man who seemed to resent the invasion of his territory by the younger physician, sought to discredit him in the eyes of the community by fomenting a malpractice suit against his rival. This covert attack was unmasked during the course of the trial and the only one discredited by the lawsuit was the doctor who promoted it.

We also have to deal with the doctor who, for a price, or from a baser motive, takes the witness stand and assumes to be an expert on matters concerning which he has little or no learning. Such a man glibly gives opinions that are oft-times ridiculous and usually reckless. Such opinion cannot be the result of an honest conviction, as the cross-examination usually discloses, but it is in the case, it is before the jury, and is a peg upon which a jury can place its verdict. It is not only the hungry lawyer, but also the hungry doctor, who is responsible for much of this litigation. We hope in the future not simply to rest content with such a record as we are able to show this year, where no case has been lost and only seven settled, but to go down deeper and take steps that will make the fomenting of this litigation anything but a pleasurable pastime for lawyers and doctors and to place the responsibility for groundless actions upon those who are responsible and to make such responsibility an undesirable load for any professional man to carry.

The discouragement of groundless malpractice actions is the duty of every physician and in performing this duty he will do a service to the profession and no injustice to any patient who has a just cause of action. We expect justice to be done the physician and we are ready, and fortunately able, to do justice to the patient who has a just complaint.

## ALOPECIA AS A RESULT OF X-RAY THERAPY

The plaintiff, a boy of about ten or twelve years of age, an inmate of an orphan asylum, was one of nine orphans in said asylum who had developed the disease of favus. All the boys had been treated medically for nine or ten months

without any apparent results from such treatment. The physician who was treating the boys had requested the defendant, an X-ray therapist, to administer X-ray treatment to the boys.

The entire scalp of the plaintiff was treated

sands of individuals are classified as licensed nurses, trained nurses, trained attendants and practical nurses, the first three classes are created under and protected by the Public Health Law of the State, the last group includes those who, for one reason or another, have failed to complete the prescribed courses in hospital training schools, and, those who never have had any hospital training whatsoever

It seems that no legal machinery exists whereby some constituted authority inspects and controls the activities of nurse registries such as is provided by the business law for other labor employment bureaus to protect the public and the registrants from improper exploitation. The former glaring evils and odious scandals in the conduct of labor employment bureaus led the public to demand their control by licensure. The underlying fundamental motives for the existence of the alumnae registries rest in the reciprocal relations with the hospital in service to its patrons, those of the registries conducted by licensed nurses rest in service to the patient and in mutual protection, while those of the commercial registry rest solely in financial gain. Registries as conducted by Registered Nurses are financed from society membership with annual dues, while commercial registries are run upon the basis of a percentage of the fees of the nurses, which naturally opens a door for irregularity and exploitation when unscrupulously conducted.

The most frequent complaint is that nurses overcharge. In order to show that the registries conducted by alumnae associations and by groups of registered nurses are not guilty of promoting excessive fees, and, that if such complaint be true and based on actual facts, the fault lies with unscrupulous nurses and with the commercial registries, a survey was made in 1923 of fees posted in registries con-

ducted by other than the commercial registries in seventeen representative cities of seventeen northern, eastern, southern and western states. The fees were scheduled under general medical and surgical service, obstetrics, contagious diseases, mental diseases, alcohol and drug addiction, the fees ranged from a minimum of \$5 00 a day to a maximum of \$11 00 a day for addicts. The rate for "24-hour duty" was \$7 00 a day in seven cities, \$6 00 a day in five cities, and \$5 00 a day in five cities, in only six cities there was a separate rate made for "12-hour duty", advances of from \$1 00 to \$4 00 per day were fairly general for obstetrical, mental, addict and contagious service. These figures indicate that the schedules for nursing service hardly have advanced in proportion to the cost of living, and, that it is not the licensed or registered nurse who is "hard-boiled"

As the professional reputation of the registered nurse seriously suffers when irregular and incompetent nursing service at exorbitant rates is supplied by the nurse registries, the New York State Nurses Association conducted an exhaustive investigation of commercial registries so that no one better than the registered nurses themselves know the conditions existing therein. To prevent professional smirching the State Nurses Association has asked co-operation and support from the physicians in a program sent to each County Medical Society for the establishment of a central registry in each community to be called the "Official Nurse Registry" upon the governing board of which shall be both physicians and lay persons. This central "Official Registry" shall register and send out for employment registered nurses, trained nurses, trained attendants and practical nurses," all of which groups shall be controlled by certain rules and regulations applicable to their own amount of experience." A T LYTL.

## NEW PROCEDURES IN MEDICINE

To what extent should physicians generally adopt the newer procedures, such as the toxin-antitoxin administration for diphtheria immunization?

We have heard public health experts question the wisdom of giving the toxin-antitoxin material to every physician that asks for it, on the ground that the composition of the mixture must be exact, and the interpretation of the results require experience and special knowledge.

Will the average doctor give the time and thought necessary to prepare himself to give the

Schick test and the toxin-antitoxin? If the doctors will not prepare themselves, then let the authorities of the Departments of Health and of Education provide the means of giving the test and the immunization at public expense.

Also, let the doctors through their county medical societies vote to support the work, and to approve the appointment of one of their number in each community who shall do the work in schools and baby clinics at public expense.

If doctors do not want to do this most excellent work in their private practice, let them direct its performance by public agencies. F O

## ALOPECIA AS A RESULT OF X-RAY THERAPY

The plaintiff, a boy of about ten or twelve years of age, an inmate of an orphan asylum, was one of nine orphans in said asylum who had developed the disease of favus. All the boys had been treated medically for nine or ten months

without any apparent results from such treatment. The physician who was treating the boys had requested the defendant, an X-ray therapist, to administer X-ray treatment to the boys.

The entire scalp of the plaintiff was treated

with X-ray, the technic used, according to defendant, being that recommended by physicians generally. However, a skin reaction followed the application of the X-ray twelve days after the treatment and the hair on the entire scalp dropped out and there was no re-growth of the hair, the plaintiff remaining completely bald, the health of the boy, however, not being affected by the X-ray.

The Adamson method of dividing up the scalp was used and the exposure on the scalp made at five separate points, each exposure at right angles to the other at each of the five points. The factors of dosage were two milliamperes, six

minutes, seventy kilowatts (equalling a six-inch spark gap on defendant's machine), eight inch skin target distance and no filters.

After examination into the authorities upon X-ray technic and consultation with various X-ray therapists, it was concluded that the dose of X-ray was excessive and caused the alopecia.

Four of the nine boys were treated with the X-ray, alopecia resulting to the four, and the favus on the other five boys cleared up under medical treatment without any loss of hair.

The claim of the four boys against the X-ray therapist was compromised and settled.

---

### ALLEGED NEGLIGENCE IN OPERATION WITH RESULTANT LOSS OF OVARY

A surgeon having performed an operation upon a woman patient was not paid for his services. Subsequently, after numerous attempts to collect his bill, he instituted an action to recover the value of his services. This case came on for trial, but resulted in a disagreement of the jury. After the trial, the patient again visited the surgeon and both she and her husband declared that they had never refused to pay him, but they were obliged to defend the action which he had instituted. The patient then asked that the surgeon make an examination of her, to determine the cause of pain at her menstrual periods, which she claimed she had been troubled with since the operation. At the time of the trial of the surgeon's action to collect for his services, it was contended on behalf of the defendant patient that a stricture of the ureter was discovered some eighteen months after the surgeon had performed his operation, it being the defendant's

contention that this condition existed at the time of the operation. The urologist to whom the patient had been referred by the surgeon testified that at the time he examined and treated the patient he discovered no stricture of the ureter and found nothing wrong with the urinary tract.

An action of alleged malpractice was instituted against the surgeon after the trial of the action to collect for the services rendered, claiming that because of the carelessness of the surgeon in the performance of the operation the plaintiff was required to submit to a further operation for the removal of an ovary and that the loss of such ovary was due to the defendant's carelessness. The action for alleged malpractice not having been commenced within two years after the performance of the defendant's operation, a motion to dismiss the complaint upon that ground was granted, favorably terminating the malpractice action in favor of the surgeon.

# State Department of Health

## SULPH-ARSPHENAMINE SUPPLIED BY DEPARTMENT

The Division of Social Hygiene is now prepared to supply physicians with sulph-arsphenamine for the treatment of indigent cases of syphilis. The State Department of Health still believes that arsphenamine is the drug of first choice where facilities are available for carrying out the proper technique of the preparation and

administration which are necessary when using this drug. Sulph-arsphenamine is primarily recommended for those cases where suitable veins are difficult or impossible to find, for children, and for use in rural communities where the proper facilities for giving arsphenamine are not available.

## DIES OF BOTULISM AFTER EATING HOME-CANNED STRING BEANS

A woman recently died in Buffalo from botulism, according to a history which was furnished the Division of Communicable Diseases by Dr. Walter S. Goodale, superintendent, Buffalo City Hospital. This woman opened a jar of home-canned string beans and ate about a tablespoonful. Her daughter tasted of these beans but owing to the disagreeable taste did not swallow any of them. The rest of the beans were discarded. On the following day the mother developed nausea and vomiting. The next day she

experienced difficulty in swallowing, in articulation and in moving the tongue, also dizziness. These symptoms increased, and there was a disturbance of vision with drooping of the eyelids. She died twelve days after eating the beans. A specimen of the discarded beans was obtained by the local laboratory. *Bacillus botulinus* was found to be present. A salt solution extract of the beans was highly toxic, 1 cc. of a 1:1000 dilution killing guinea pigs within 12 hours.

## CURED OR ARRESTED?

The conference of Venereal Disease Control Officers of the State Departments of Health and the United States Public Health Service which met in Hot Springs, Arkansas, in December, went on record as advocating a more careful use of the word "cure" in relation to the treatment of syphilis.

A news release of the United States Public Health Service concerning this conference states that

The indiscriminate use of the word "cure" in the treatment of syphilis should be discontinued and instead the patient should be made to think merely of an

arrested condition as in tuberculosis. Persons undergoing treatment for syphilis should expect and seek observational control at appropriate intervals and under proper medical care through a period of years—instead of considering themselves cured after a few months or a year's treatment in order to avoid late involvement of the heart, blood vessels and nervous system.

A complete comprehensive report of this conference dealing with recommendations for the policy, management, methods and standards of examination, diagnosis and treatment of syphilis for clinics is to be sent to all upstate physicians by the Division of Social Hygiene of the State Department of Health.

## ANOTHER POST-DIPHTHERITIC DEATH FROM CARDIAC INVOLVEMENT

Another sudden death following diphtheria was recently added to the considerable number which have already been reported. In this case the patient was a boy of five. The report states that a physician saw him on the first day of the disease but as no membrane was observed, antitoxin was not given until two days later. Only a very slight membrane, confined to the tonsils, appeared during the course of the illness. It cleared up rapidly

after use of antitoxin. The child was apparently well, and was up and about his room. He died suddenly, following some unusual exertion.

This case not only illustrates the need of the early administration of antitoxin, even in mild cases, but it also shows that greater care is called for in keeping patients in bed for a longer period, especially in cases where antitoxin is administered later than the first day of the disease.

## DEMAND FOR STERILE OBSTETRIC PACKAGES GROWS

The public health nurse for the city of Beacon reports that the call for sterile obstetric packages is increasing so fast that the local Red Cross Society find it difficult to keep up with the demand.

The Century Club of Amsterdam has given fifty dollars to the local public health nurse to be used in purchasing material for the packages and the club has arranged to help in preparing them.

with X-ray, the technic used, according to defendant, being that recommended by physicians generally. However, a skin reaction followed the application of the X-ray twelve days after the treatment and the hair on the entire scalp dropped out and there was no re-growth of the hair, the plaintiff remaining completely bald, the health of the boy, however, not being affected by the X-ray.

contention that this condition existed at the time of the operation. The urologist to whom the patient had been referred by the surgeon testified that at the time he examined and treated the patient he discovered no stricture of the ureter and found nothing wrong with the urinary tract.

An action of alleged malpractice was instituted against the surgeon after the trial of the action to collect for the services rendered, claiming that because of the carelessness of the surgeon in the performance of the operation the plaintiff was required to submit to a further operation for the removal of an ovary and that the loss of such ovary was due to the defendant's carelessness. The action for alleged malpractice not having been commenced within two years after the performance of the defendant's operation, a motion to dismiss the complaint upon that ground was granted, favorably terminating the malpractice action in favor of the surgeon.

2 Those of medical extension, or of an academy of medicine

- (a) library,
- (b) graduate education

The activities of the Society during 1924 are set forth in a report of thirty-four pages on the size of this Journal. Nine pages are devoted to lists of members and the personnel of the committees, and eight to the Library. This report is made annually, and is unique among county medical societies.

The Society holds eight meetings a year on the third Tuesday evening of each month except during the summer. The average attendance is between two hundred and three hundred. The major affairs of the Society are settled at the meetings, and debates sometimes continue until one or two o'clock in the morning. The Society is entirely democratic in its methods of conducting its affairs.

The programs of the meetings during the last year or two have been on topics of civic medicine, for the scientific work of the Society is conducted through its organized graduate education system.

The Society carries on its routine affairs largely through its council of officers and its committees. In addition to the usual ones which manage the internal affairs, the Society has committees which carry out important lines of civic policies.

The Committee on Legislation has been unusually active, and has impressed itself on the members of the Legislature. While its decisions have not always coincided with the policies of majority of the legislative committees of other county societies, yet the amount of work done has been monumental, and the high motives of the members have been unquestioned.

A committee on Illegal Practice has set the pace for ferreting out quacks and securing evidence against those who practice medicine without licenses. It has worked in close harmony with the District Attorney, and holds an enviable record in the enforcement of the Medical Practice Law in Brooklyn.

One of the most important committees has been that on Public Health. This committee has been extremely active and has cooperated with other health agencies, among which are the Health Department, the Committee on Dispensary Development, the Associated Out-Patient Clinics, the Visiting Nurses' Association, the Maternity Center Association, and the Brooklyn Tuberculosis Committee. Many of its studies have been similar to those made by academies of medicine in other large cities, and its expenses have been largely met by voluntary contributions. The Committee has promoted the idea that organizations of practicing physicians are

the natural bodies that should take the lead in all lines of work which have to do with health, and it has succeeded in its ideals to a remarkable degree.

An outstanding accomplishment of the Committee on Public Health has been an extensive demonstration of Periodic Health Examinations which were described on page 739 of the June, 1924, issue of this journal. The work of this Committee has attracted the notice of public health workers throughout the nation.

The Milk Commission of the Society directs the production of certified milk, and is probably the most active and efficient in New York State. It maintains corps of inspectors under its director, Dr. Harris A. Moak, and supervises 14 dairies. Its laboratory work is done at 360 Park Place, Brooklyn.

The Society has an active Visiting Committee whose object is to call on sick members of the Society.

The Historical Committee, under the chairmanship of Dr. William Schroeder, has done an immense amount of biographical work relating to both new and deceased members.

The Committee on Medical Economics has considered matters concerning the relation of physicians to other organizations, such as insurance companies and the State Compensation Commission. It has also spoken for the medical profession in the relation of physicians to lay public health organizations, such as the Brooklyn Maternity Center Association.

A Committee on Press Reference was appointed during the past year for the purpose of giving authoritative statements on medical subjects to daily newspapers when medical news stories develop. The Society gave one of its regular meetings to a discussion of this subject, and the editors of all the daily papers in Brooklyn were present and spoke in favor of the project. The Committee has received recognition from the newspapers, and the only difficulty in the way of an extensive use of the service seems to be the impatience of the editors to publish news before the physicians have time to investigate the stories. The Committee has also worked in cooperation with the Committee on Publicity.

Another object of the Committee was to prepare medical articles for the newspapers to publish. According to the report of the Committee the reason that few of its articles have been published has been that the articles submitted to the committee have been too technical for the lay reader. The report concludes "It is our hope that, during the year to come, we shall be able to gather a series of articles for publication which will be of benefit to the community which we serve."

# MEDICAL SURVEY

## MEDICAL SURVEY NUMBER 9 MEDICINE IN KINGS COUNTY

**EDITOR'S NOTES** —The information on which this Survey is based was obtained through the cooperation of Dr John E Jennings, President of the Medical Society of the County of Kings, and Dr Alec N Thomson, Secretary of the Public Health Committee of the Society

Kings county forms one of the Boroughs of Greater New York, and constituted the city of Brooklyn previous to the formation of the city of Greater New York. It is located on the south-west end of Long Island, and has an area of about 71 square miles. Its population is about 2,200,000, according to the estimates used by the New York City Department of Health. It is almost equal to the population of Manhattan, and at its present rate of growth, will soon exceed that of Manhattan.

**PHYSICIANS** The number of physicians in Kings County is 2631, according to the Directory of the Medical Society of the State of New York. This gives a proportion of one physician to every 835 inhabitants. This proportion is nearly double that of Manhattan where there is one doctor to every 432 of population, but the proportion in the Bronx Borough is one to 950, in Queens, one to 1220, in Richmond, one to 1300. In New York State outside of Greater New York there is one doctor to every 770 of population.

The practice of medicine in Brooklyn partakes of the nature of practice in small cities to greater extent than in any other great city. The reasons for this fact are two fold.

First Brooklyn is a city of homes in contrast with Manhattan which is a great commercial center for the whole nation.

Second Brooklyn has developed from a group of isolated villages which grew and extended their boundaries until they fused themselves into one big city, but each section has retained much of its own individuality.

The peculiar manner of development of Brooklyn is reflected in the medical professions. The physicians of Brooklyn have the characteristics of family physicians to a greater extent than those of any other great city. The city is well supplied with specialists and consultants, the majority of whom have risen from the ranks of general practitioners, and have retained their intimate associations with family doctors.

Brooklyn has developed medically as if it were an independent unit separated a hundred miles from the rest of New York City. It has a Class A medical school, an extremely active

county medical society, and a medical library which ranks among the half dozen greatest in the United States. It is also the medical center for the rest of Long Island with about 800,000 population and 800 physicians.

**MEDICAL SOCIETIES** The principal medical organization of Brooklyn is the Medical Society of the County of Kings, which is an integral part of the Medical Society of the State of New York. The County Society has 1578 members, or 60 per cent of the physicians who are listed in the Directory of the State Medical Society. This proportion of membership is about the same as that in all of Greater New York and throughout the State. The Society added 145 new members in the past year.

The Medical Society of the County of Kings combines the functions of a county medical society with those of an academy of medicine. It owns its own building, maintains its own library, conducts graduate education work, and performs other functions which are usually assumed by an Academy of Medicine. The medical organizations of Brooklyn are unified to greater extent than in any other county of the State.

The Society has recently adopted a sliding scale of dues according to the year of graduation of the members. Those who have graduated recently and are not yet established in a large practice, pay yearly dues of ten dollars, in addition to the State dues, while those who have been a considerable time in practice and have had an opportunity for financial gain, pay twenty-five dollars. The plan is working satisfactorily.

**SOCIETY BUILDING** The building now occupied by the County Medical Society is located at 1313 Bedford avenue, within one block of the Nostrand Avenue Station of the Long Island Railroad. It was built in 1898, and its value is rated at \$100,000. The funds were raised by subscriptions given by Brooklyn physicians and their friends. The building houses the Library and Reading Room, and contains an Assembly Hall which seats 450 persons. Plans are being perfected for an addition which will double the present capacity of the building.

The activities of the Medical Society of the County of Kings may be classified as follows:

1 Those common to all county medical societies

- (a) meetings,
- (b) committee work.

2 Those of medical extension, or of an academy of medicine

- (a) library,
- (b) graduate education

The activities of the Society during 1924 are set forth in a report of thirty-four pages of the size of this Journal. Nine pages are devoted to lists of members and the personnel of the committees, and eight to the Library. This report is made annually, and is unique among county medical societies.

The Society holds eight meetings a year, on the third Tuesday evening of each month except during the summer. The average attendance is between two hundred and three hundred. The major affairs of the Society are settled at the meetings, and debates sometimes continue until one or two o'clock in the morning. The Society is entirely democratic in its methods of conducting its affairs.

The programs of the meetings during the last year or two have been on topics of civic medicine, for the scientific work of the Society is conducted through its organized graduate education system.

The Society carries on its routine affairs largely through its council of officers and its committees. In addition to the usual ones which manage the internal affairs, the Society has committees which carry out important lines of civic policies.

The Committee on Legislation has been unusually active, and has impressed itself on the members of the Legislature. While its decisions have not always coincided with the policies of majority of the legislative committees of other county societies, yet the amount of work done has been monumental, and the high motives of the members have been unquestioned.

A committee on Illegal Practice has set the pace for ferreting out quacks and securing evidence against those who practice medicine without licenses. It has worked in close harmony with the District Attorney, and holds an enviable record in the enforcement of the Medical Practice Law in Brooklyn.

One of the most important committees has been that on Public Health. This committee has been extremely active and has cooperated with other health agencies, among which are the Health Department, the Committee on Dispensary Development, the Associated Out-Patient Clinics, the Visiting Nurses' Association, the Maternity Center Association, and the Brooklyn Tuberculosis Committee. Many of its studies have been similar to those made by academies of medicine in other large cities, and its expenses have been largely met by voluntary contributions. The Committee has promoted the idea that organizations of practicing physicians are

the natural bodies that should take the lead in all lines of work which have to do with health, and it has succeeded in its ideals to a remarkable degree.

An outstanding accomplishment of the Committee on Public Health has been an extensive demonstration of Periodic Health Examinations which were described on page 739 of the June, 1924, issue of this journal. The work of this Committee has attracted the notice of public health workers throughout the nation.

The Milk Commission of the Society directs the production of certified milk, and is probably the most active and efficient in New York State. It maintains corps of inspectors under its director, Dr. Harris A. Moak, and supervises 14 dairies. Its laboratory work is done at 360 Park Place, Brooklyn.

The Society has an active Visiting Committee whose object is to call on sick members of the Society.

The Historical Committee, under the chairmanship of Dr. William Schroeder, has done an immense amount of biographical work relating to both new and deceased members.

The Committee on Medical Economics has considered matters concerning the relation of physicians to other organizations, such as insurance companies and the State Compensation Commission. It has also spoken for the medical profession in the relation of physicians to lay public health organizations, such as the Brooklyn Maternity Center Association.

A Committee on Press Reference was appointed during the past year for the purpose of giving authoritative statements on medical subjects to daily newspapers when medical news stories develop. The Society gave one of its regular meetings to a discussion of this subject, and the editors of all the daily papers in Brooklyn were present and spoke in favor of the project. The Committee has received recognition from the newspapers, and the only difficulty in the way of an extensive use of the service seems to be the impatience of the editors to publish news before the physicians have time to investigate the stories. The Committee has also worked in cooperation with the Committee on Publicity.

Another object of the Committee was to prepare medical articles for the newspapers to publish. According to the report of the Committee the reason that few of its articles have been published has been that the articles submitted to the committee have been too technical for the lay reader. The report concludes "It is our hope that, during the year to come, we shall be able to gather a series of articles for publication which will be of benefit to the community which we serve."

**THE LIBRARY** The library of the Medical Society of the County of Kings ranks third among the medical libraries of the Nation in point of age, fifth in actual size, and second to none in usefulness. It was founded in 1844 through the contributions of the physicians of Brooklyn. It now has 100,000 volumes and is increasing at the rate of 3,000 volumes annually. It is now exceeded in number of volumes by only the following four medical libraries in the country: The Library of the Surgeon General's office in Washington, the Philadelphia College of Physicians, the New York Academy of Medicine, the Boston Medical Library.

The library is housed in the modern fireproof building of the County Medical Society, but its space is crowded like that of the other large medical libraries.

The library employs a full-time librarian, Mr. Charles Frankenberger, who, with his staff of three assistants, is active and efficient in the management and enlargement of the library in assisting physicians in its use.

The library has no large endowment, but it is supported almost entirely from medical sources. A Medical Library Association is an auxiliary organization, which has been in existence since 1903 and which was formed for the purpose of applying its dues to the support of the library, and the influence of its members to the promotion of the interests of the library. There are a dozen organizations of specialists that subscribe to periodicals and books which are presented to the library, the *Long Island Medical Journal* brings in over 400 periodicals in exchanges from all over the world, and the new books from its book review department, the Brooklyn Dental Societies also contribute literature. While no one source of support is great, yet the aggregate of the smaller contributions from purely medical sources enables the library to keep fully abreast of the times.

The library is maintained for practical use, and in order to increase its efficiency the principal current periodicals (total number received, 1,016), and the review books are kept in the reading room on shelves which are accessible to physicians without their needing to consult the library staff. This service enables a physician to browse in his own way among the newer medical periodicals and books.

**GRADUATE EDUCATION** The County Medical Society conducts an extensive system of graduate medical education work along two lines: first, a series of lectures, and second, organized clinical courses.

The object of both the lectures and the clinical courses has been to instruct general practitioners in the art and science of the practice of clinical medicine. The teaching specialists

have tried to give family doctors a broad insight into conditions which require expert attention, realizing that the ordinary physician must know the fundamentals of a dozen or more specialties. The point of view of the teachers may be illustrated by the instruction on hearts. Instead of giving lectures on "The Surgery of the Heart Valves" they were upon "The Cardiac Patient."

The lectures are in charge of a special committee, and are given by prominent men who are noted for their ability in teaching and lecturing as well as their scientific attainments. They are given in the Society's building on Friday afternoons at five o'clock, and each one has been attended by over four hundred doctors. The Assembly Room has always been filled to overflowing. The series is commonly known as the "Five o'Clock Lectures."

The series of lectures have been completed, and two have been published in book form. The 1924 series consisted of twenty lectures, the first five of which were as follows:

Dr. George D. Stewart, "The Gall Bladder"

Dr. Foster Kennedy, "Fits,"

Dr. Haven Emerson, "Periodic Health Examinations,"

Dr. James T. Case, "The Colon,"

Dr. Harold E. B. Pardee, "The Cardiac Patient"

The 1923 volume of lectures is a practical classic on the management of common conditions which every physician meets, and the 1924 volume promises to be equally good.

The teaching clinics have been arranged by a joint committee of the Medical Society of the County of Kings and the Long Island College Hospital Medical School. They are held in eleven hospitals which can supply patients and teaching equipment. The hours of instruction are suited to the classes, and many meet at four o'clock. The object is to enable physicians to attend the courses without interrupting their practice. The courses are printed in a catalogue and appendices are issued monthly. The 1924 enrollment was 163 physicians.

The Committee has offered to extend the courses to the rural sections of Long Island, and a class in pediatrics has been formed with 25 members who meet weekly in the South Side Hospital in Bay Shore. Other classes are being formed in other rural parts of the Island.

The Brooklyn clinics set a new standard in graduate education, and are conducted on this simple principle: "Here is a group of doctors who desire practical instruction along a specific line. Give it to them at their convenience."

**GROUP MEDICAL SOCIETIES** The Medical Society of the County of Kings has not formed sections in the several branches of medicine, but

those who practice the various specialties have formed group societies, such as those in ophthalmology, gynecology, surgery, urology, dermatology, pediatrics, pathology, neurology, and internal medicine

The physicians of Brooklyn have also formed societies along geographic lines which largely coincide with those of the villages into which Brooklyn was formerly divided. Among the important local societies which are active are those of Bay Ridge, Flatbush, Williamsburg, East New York, New Utrecht, North Brooklyn, and Greenpoint.

The physicians of Brooklyn came in close touch with those from other parts of Long Island through the Associated Physicians of Long Island, and the Second District Branch of the Medical Society of the State of New York. The Associated Physicians performs nearly all the functions which a district branch is expected to perform. It holds three meetings a year, and exerts a great influence on medical affairs throughout the Island. It has about 1,000 members, over two-thirds of whom come from Brooklyn.

**THE LONG ISLAND MEDICAL JOURNAL.** The Associated Physicians of Long Island publishes a monthly journal, the Long Island Medical Journal, whose pages are open to any group of physicians on Long Island. It has promoted the activities of the Medical Society of the County of Kings to a greater extent than those of any other society, and might almost be considered to be the organ of the County Society.

**THE BULLETIN.** The Medical Society of the County of Kings publishes a four-page monthly Bulletin containing announcements of the meetings and other activities of the Society. It is written in a sprightly style of compelling interest.

**THE MEDICAL SCHOOL.** Brooklyn has a medical school—The Long Island College Hospital Medical School—which is listed as Class A, and which has trained some of the most prominent physicians of the City. It was founded in 1854, and has always had a deep influence in local medical affairs. It has cooperated with the County Medical Society in offering instruction to practicing physicians. The members of its staff are active in the local societies, and in the practice of medicine, and thereby they maintain a practical point of view which is reflected in their teaching.

The medical school utilizes several hospitals for teaching, but tentative plans are under way to associate the medical school with the Kings County Hospital, and thus form one of the greatest medical teaching centers in the world. The Kings County Hospital is a part of the Municipal Hospital System of Greater New York. It is located in about the center of Brooklyn, adjoining the grounds of the Kingston Avenue Contagious

Disease Hospital and the Brooklyn State Hospital for the Insane. The three groups cover over 40 city blocks, and have a capacity of 4,000 beds for every known disease. These form a ready-made medical center which is adapted to giving instruction better than any other center in the world. The Brooklyn physicians are developing the plans for a greater medical school quietly yet effectively.

**HOSPITALS.** Brooklyn is well supplied with hospitals. When the American College of Surgeons met in Greater New York in 1924, the managers of the hospitals of Brooklyn formed a Council for the purpose of coordinating their efforts to entertain the visiting surgeons. Their work proved to be so valuable to the hospitals themselves that the Council was continued. The Council has representatives from all the general hospitals in Brooklyn, and twenty-three hospitals are listed as members.

The total number of beds in the hospitals of the Council is 6,300, of which 1,800 are in the Kings County Hospital, the largest in the city. This gives a proportion of about three beds for every one thousand inhabitants. But the number of beds available for the sick is much greater than this, for the Council includes only the larger and better equipped hospitals.

Eleven of the hospitals are listed as teaching hospitals, and clinics are given in them under the auspices of the Joint Committee on Graduate Education.

The Long Island College Hospital is an integral part of the Medical School, and much of the clinical instruction of the students is given in the amphitheaters of the operating rooms.

**DISPENSARIES.** The Public Health Committee of the Medical Society of the County of Kings has cooperated with the Hospital Council to raise the standards of the dispensaries to those of the hospitals. Many of the hospitals belonging to the Council conduct outpatient departments, and are trying to secure the adoption of standards which shall include an organized staff of competent physicians, a complete record of every case, adequate laboratory service, and proper services along nursing, social, and clerical lines. The object is to place dispensary service on the same high plane as that of a first-class hospital.

**VISITING NURSING.** Brooklyn has a Visiting Nursing Association with headquarters at 80 Schermerhorn Street. It has a corps of 90 graduate registered nurses who give skilled care to the sick in their homes, and teach families how to keep well. The nurses work from 8 30 A. M. to 5 30 P. M., and charge a fee of one dollar for each visit to those who are able to pay, but no one is refused on account of lack of funds.

**THE LIBRARY** The library of the Medical Society of the County of Kings ranks third among the medical libraries of the Nation in point of age, fifth in actual size, and second to none in usefulness. It was founded in 1844 through the contributions of the physicians of Brooklyn. It now has 100,000 volumes and is increasing at the rate of 3,000 volumes annually. It is now exceeded in number of volumes by only the following four medical libraries in the country: The Library of the Surgeon General's office in Washington, the Philadelphia College of Physicians, the New York Academy of Medicine, the Boston Medical Library.

The library is housed in the modern fireproof building of the County Medical Society, but its space is crowded like that of the other large medical libraries.

The library employs a full-time librarian, Mr. Charles Frankenberger, who, with his staff of three assistants, is active and efficient in the management and enlargement of the library in assisting physicians in its use.

The library has no large endowment, but it is supported almost entirely from medical sources. A Medical Library Association is an auxiliary organization, which has been in existence since 1903 and which was formed for the purpose of applying its dues to the support of the library, and the influence of its members to the promotion of the interests of the library. There are a dozen organizations of specialists that subscribe to periodicals and books which are presented to the library, the *Long Island Medical Journal* brings in over 400 periodicals in exchanges from all over the world, and the new books from its book review department, the Brooklyn Dental Societies also contribute literature. While no one source of support is great, yet the aggregate of the smaller contributions from purely medical sources enables the library to keep fully abreast of the times.

The library is maintained for practical use, and in order to increase its efficiency the principal current periodicals (total number received, 1,016), and the review books are kept in the reading room on shelves which are accessible to physicians without their needing to consult the library staff. This service enables a physician to browse in his own way among the newer medical periodicals and books.

**GRADUATE EDUCATION** The County Medical Society conducts an extensive system of graduate medical education work along two lines: first, a series of lectures, and second, organized clinical courses.

The object of both the lectures and the clinical courses has been to instruct general practitioners in the art and science of the practice of clinical medicine. The teaching specialists

have tried to give family doctors a broad insight into conditions which require expert attention, realizing that the ordinary physician must know the fundamentals of a dozen or more specialties. The point of view of the teachers may be illustrated by the instruction on hearts. Instead of giving lectures on "The Surgery of the Heart Valves" they were upon "The Cardiac Patient."

The lectures are in charge of a special committee, and are given by prominent men who are noted for their ability in teaching and lecturing as well as their scientific attainments. They are given in the Society's building on Friday afternoons at five o'clock, and each one has been attended by over four hundred doctors. The Assembly Room has always been filled to overflowing. The Brooklyn clinics set a new standard in graduate education, and are conducted on this simple principle: "Here is a group of doctors who desire practical instruction along a specific line. Give it to them at their convenience."

**GROUP MEDICAL SOCIETIES** The Medical Society of the County of Kings has not formed sections in the several branches of medicine, but

# NEWS NOTES

## ANNUAL MEETING

### TUBERCULOSIS SESSION

Thursday, May 14th, Hotel Syracuse

#### Sub-Committee in Charge of Demonstration

EDWARD R. BALDWIN, M.D., *Honorary Chairman*  
HARRY A. BRAY, M.D., *Chairman*

HARRY J. BRAYTON, M.D.  
WILLIAM E. LAWSON, M.D.

JOHN J. LLOYD, M.D.

#### Part One—Morning

##### DEMONSTRATION SESSION

###### Pathological

###### FRESH SPECIMENS

- (a) Demonstration of gross and microscopic specimens of human tuberculosis
- (b) Demonstration of gross and microscopic specimens of bovine tuberculosis  
Victor Moore, M.D., Cornell University, Ithaca.

###### BACTERIOLOGICAL

State Department of Health, Division of Laboratories

- (a) Cultures of pathogenic acid-fast bacilli
- (b) Various preparations of tuberculin
- (c) Methods of staining the tubercle bacilli, in urine, sputum and feces

###### X-RAY SESSION

- (a) Tuberculosis in infants  
Bela Schick, M.D., New York City
- (b) Tuberculosis in childhood.  
Henry D. Chadwick, M.D., Westfield Sanatorium, Mass.
- (c) Technic of X-ray exposures of the chest.
- (d) Demonstration of stereoscopic films
- (e) Interpretation of chest radiograms  
J. J. Lloyd, M.D., and Associates, Monroe Co. Tuberculosis Sanatorium, Rochester, N. Y.
- (f) Radiogram in intestinal tuberculosis  
Frederick H. Heise, M.D., Homer L. Sampson, Trudeau Sanatorium, Trudeau, N. Y.
- (g) Pulmonary tuberculosis—moving pictures
- (h) Demonstration charts of moving pictures  
L. Gregory Cole, M.D., New York City

###### PHYSICAL DIAGNOSIS

- (a) Demonstration of physical signs by the stethophone and other methods  
H. J. Brayton, M.D., and Associates, Onondaga San., Syracuse, N. Y.

###### HELIO THERAPY

- (a) Demonstration of work by representatives of J. N. Adam Memorial Hospital, Perrysburg, N. Y.
- (b) Application of mercury quartz lamp in treatment of laryngeal, intestinal lymphatic, bone and joint tuberculosis  
Edgar Mayer, M.D., Saranac Lake, N. Y.

#### DISCUSSION OF PARTICULAR LESIONS

- (a) Surgical—  
Tuberculosis of the bones  
Tuberculosis of the glands.
- (b) Skin manifestations of tuberculosis  
Schuyler P. Richmond, M.D., Syracuse, N. Y.
- (c) Tuberculosis of the eye.  
Arthur J. Bedell, M.D., Albany, N. Y.
- (d) Tuberculosis of the larynx.
- (e) Tuberculosis in pregnancy
- (f) Tuberculosis of the genito-urinary tract  
Henry G. Bugbee, M.D., New York City

#### CLINICAL AND HOSPITAL FACILITIES

Portable clinics  
County hospitals  
Vital statistics  
State Department of Health, Division of Tuberculosis  
Public health clinics and demonstrations  
By the Milbank Foundations  
County tuberculosis committee work. By the State  
Charities Aid Association.

#### ERADICATION OF BOVINE TUBERCULOSIS

Division of Farms and Markets

#### LIBRARY REFERENCES

Books, Periodicals and Journals  
State Department of Education, Medical Library, Miss  
Frances K. Ray

#### Part Two

##### SCIENTIFIC SESSION

###### Diagnosis

- (a) History and symptoms  
David R. Lyman, M.D., New Haven, Conn.
- (b) Physical signs  
Henry B. Doust, M.D., Syracuse.
- (c) X-ray diagnosis  
J. B. Amberson, Jr., M.D., Loomis Sanitarium, Loomis

###### SURGICAL TREATMENT

- (a) Pneumothorax.  
Edward N. Packard, M.D., Saranac Lake.
- (b) Phrenectomy and thioracoplasty

###### TREATMENT BY HELIO THERAPY

Horace L. Grasso, M.D.,  
J. N. Adams, Memorial Hospital, Perrysburg  
Note: The addresses will be limited to 15 minutes  
The discussions will be limited to 3 minutes

The Association also supports 12 orthopedic nurses who visit cases suffering with infantile paralysis and other orthopedic conditions. The Association is endorsed by the Medical Society of the County of Kings. It prepared a four-page folder describing the nursing service, and sent a copy to every physician in the city. A unique feature of the folder was a set of standing orders to which the Association had agreed. The orders enumerate the procedures which a nurse may follow without being considered to practice medicine. The following paragraph illustrates the scope of the orders:

"For infants and children with fever undiagnosed,—confine to bed, colonic irrigation with salt solution,—soda bicarb. Give boiled water. For infantile convulsions, give hot mustard bath, (tablespoonful of mustard to one gallon of water) no food."

The nursing service is becoming increasingly popular and appreciated by the Physicians of Brooklyn.

**TUBERCULOSIS WORK** The Brooklyn Bureau of Charities, at 69 Schermerhorn Street, acts as the Tuberculosis Committee of Brooklyn. The Bureau obtains most of its tuberculosis funds by the sale of Christmas Seals which it obtains directly from the National Tuberculosis Association. Among its other activities the Bureau supports two tuberculosis clinics, a nutritional clinic, and a summer camp for undernourished children.

The Tuberculosis Committee provided the funds for the periodic health examination demonstration of the Medical Society of the County of Kings, and has carried on an intensive campaign to popularize the examination.

The Bureau does a large amount of work in assisting needy families along many lines besides those of financial relief. It has found that sickness is the most common single cause of dependency and it gives prominence to those lines of relief work which have a medical bearing.

**THE BROOKLYN CHILDREN'S AID SOCIETY** The Brooklyn Children's Aid Society has offices at 72 Schermerhorn Street. It provides milk to the twenty-five Baby Health Stations of the City, and follows up the babies in their homes. It supports the Wave Crest Convalescent Home

at Far Rockaway for the post-operative care of children from the various hospitals. It has a capacity of 50 beds, which will soon be increased by 120 additional beds.

**BROOKLYN SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN** This Society is active in all phases of work among children which are neglected or abused. Its work is largely medical, but it is one of the principal legal agencies for the care and control of children who are either "Bad" or are the victims of unsocial environments.

**THE CHAMBER OF COMMERCE** The Brooklyn Chamber of Commerce has many activities which have important effects on health. It furnishes a strong combination of professional men and laymen helping toward the maintenance and improvement of the public health. It has a committee on Public Health which has made extensive investigations into methods of the disposal of garbage and sewage. The Committee has investigated the causes of loss of life from the inhalation of illuminating gas, since this is the second largest cause of accidental loss of life in Brooklyn.

A special committee carries on a continuous campaign for a "cleaner Brooklyn."

**IN CONCLUSION** We have sketched medical conditions in Brooklyn in outline only. The physicians of Brooklyn form an independent body of doctors who have always done their own thinking, and have developed many progressive ideas along original lines. One item of progress has been that of raising the standards of the art and science of the practice of medicine by the entire body of physicians. Another has been the promotion of the practice of civic medicine by the County Medical Society. Another has been the insistence that physicians shall be prominent advisors of lay organizations having health objects.

Modesty is a characteristic of Brooklyn doctors and their organizations, and they are poor advertisers. Their policy has been "If a thing needs doing, go and do it without talking about it." The Brooklyn physicians have not done any one thing in a spectacular way, but they have accomplished a great mass of detailed work which is a model for physicians elsewhere.

F O

## GORGAS MEMORIAL

It is "The Gorgas Idea" to give to every individual the heritage of good health to which he is entitled by means of

Scientific research into the cause, prevention and cure of disease

The application of such preventive and curative measures as may be necessary under the supervision of the leaders in scientific medicine

Saving to the world the present economic loss in human resources from preventable disease

Preventing the stupendous economic loss resulting from sickness, ill health and preventable deaths

Transforming disease infested localities into fertile and productive areas thus increasing the wealth of the individual and the nation

William Crawford Gorgas devoted his life to the practical demonstration of scientific theories along preventive and curative lines with the far-reaching results so familiar to every man and woman of this day. The methods established by him at Cuba and Panama completely eradicated yellow fever from these hotbeds of the disease. As a result, our own southern states are forever rid of the horrors of "yellow jack," which, before his time, cost so many human lives and billions of dollars. In one well-remembered epidemic in the Mississippi Valley the toll was 13,000 lives and an economic loss of hundreds of millions of dollars.

As Surgeon General of the United States Army during the great War, with the responsibility of the health and physical well-being of five million men on his shoulders, he demonstrated the value of periodical medical examinations for the purpose of revealing incipient and unsuspected diseases. The statistics of the War Department reveal that this procedure, coupled with prompt application of the necessary curative measures when illness did develop, succeeded in keeping five million men exposed to the hardships of camp life in better condition physically than a like number in civil life.

For many months physicians and surgeons and laity throughout the United States have been endorsing the movement to perpetuate the name of William Crawford Gorgas in the organization known as the Gorgas Memorial whose twofold aim may be inferred from the above, namely, scientific research in the Gorgas Institute in Panama and everywhere to disseminate health information by means of the press, magazine articles, the lecture platform, the radio and motion picture films, particularly emphasizing the importance of periodic health examinations by the family doctor.

Of interest to all connected with the Gorgas Memorial is a recent announcement by Dr. D. M.

Gallie, Chairman of the Gorgas Committee for the American Dental Association, and Dr. W. H. G. Logan, Secretary of the Gorgas Memorial Institute that the 35,000 dentists who are members of the American Dental Association have joined hands with the physicians and surgeons of the Gorgas Memorial Institute in a nation-wide effort to cut down the 25,000 cases of illness which occur every year in the United States.

According to Dr. Logan, who is both physician and dentist, at least 87 per cent of the people are in need of dental care. A large number have dangerous mouth infections which are apt to cause serious ills in later life.

"Disease germs," explained Dr. Logan, "breed in the mouth on the twenty to thirty inches of teeth surface, in between the teeth, about their roots and in the tonsils. As long as infection is present, there is a continuous flow of poisons which may result in damage to the vital organs of the body, so that a person's life may be cut short many years."

"Besides rheumatism, certain kinds of heart trouble, kidney trouble and a generally lowered resistance, which makes it possible for other disease germs to attack the body, infected teeth can result in many lesser aches and pains. Neuralgia, insomnia and a general breakdown are many times due to mouth infections."

"Periodic physical examination sponsored by the Gorgas Memorial Institute daily reveal cases which need dental treatment. When the dentist discovers an infected mouth, he knows that the patient often needs medical attention as well, so as to counteract the damage done by disease germs from his mouth."

"Thus by working together for a common cause, the physician and dentist will be able to detect the real cause of a patient's illness, and to remove the cause, thereby prolonging life and sustaining health for the individual."

Dr. George David Stewart, Chairman of the New York City Executive Committee of the Gorgas Memorial, reports an overwhelming number of letters in response to his recent talk over radio station WEAJ, when he outlined the purposes of the Gorgas Memorial. Mr. George F. Baker, Jr., listening in, sent his personal check for \$1,000 to Dr. Stewart "for the splendid preventive effort in which you and other men in the medical profession are interested."

"It seems to me," added Mr. Baker, "that you fellows (of the scientific medical profession) are all the time thinking of things for the benefit of humanity."

The Gorgas Memorial appreciates the generosity of Mr. Baker and congratulates him on his sentiments regarding the medical profession. We trust that others follow his example.

## THE MEDICAL SOCIETY OF THE COUNTY OF QUEENS

A regular meeting of the Medical Society of the County of Queens was held Tuesday evening, March 31, 1925, at Eagle Palace, Jamaica, at 9 00 P M., with the president, Dr Courten, in the chair

The minutes of the previous meeting were read and approved as corrected The following candidates for membership were presented

David B Blumenfeld, M D, Woodhaven,  
Peter A E Saponaro, M D, Astoria, Irving  
Singer, M D, Jamaica

By resolution the secretary was instructed to cast one ballot for the election of the candidates

Dr McMahon, Chairman of the Legislative Committee, reported as to the fate of the several bills in which the society was interested in the legislative assembly of the state Dr Steffen offered an amendment to the by-laws, providing that the name of the Committee on Publicity and Public Health Instruction be changed to Committee on Publicity

Moved and seconded that the amendment be adopted

Dr Steffen asked that the members of the society send into the Committee on Publicity before the 10th of each month items of news, reports of hospital meetings, etc., for publication in the bulletin

Dr Luther F Warren, Professor of Medicine at the Long Island College Hospital, presented a paper on "The Pneumonias"

After giving a brief history of the different forms of treatment for the disease, and giving data to emphasize the importance of the subject, the chief part of the paper was an interesting and instructive review of the work done at the Long Island College Hospital, and at other clinics with the various forms of modern specific treatment

The use of type I serum in patients suffering from pneumonia of that type was followed with fair regularity by a fall of temperature, and an improvement in the general condition lessening of pain, malaise, cyanosis and dyspnoea, and the clinics where the treatment has been used report a lower mortality rate

The serum is given in 50 c.c. or 100 c.c. doses repeated at varying intervals until usually about 10 c.c. is administered, introduced slowly and treatment is pre-  
t has been used report  
essary

serum treatment is the  
actions—chill and rise of  
ns of serum disease, occur-  
cent of cases treated, viz.,  
ns, adenitis or arthritis, all  
current In an attempt to

avoid this disadvantage the use of antibody solution was introduced but has proved ineffectual in sterilizing the blood stream or influencing the course of the disease

Dr Warren is of the opinion that the use of vaccine is of some benefit in those cases running a more prolonged course

Under the topic of abortive treatment, the reader expressed the opinion that urotropin, camphor and quinine are of value if administered early

Dr Carl Eggers, Surgeon at Lenox Hill Hospital, in his paper on the Surgical Complications of Pneumonia, confined his remarks chiefly to Empyema

The mortality rate of this condition varies from 1-2 per cent to 25 per cent, variations depending on differences in virulence of organism, in individual resistance and on type and time of operation

Careful study of each individual patient is required, including typing of organism present

Not all fluids are infected, and many clear spontaneously or by tapping, not all infected fluids are empyemata

Empyemata complicating lobar pneumonia are usually confined to pleura overlying affected lobe, soon become thick, and evacuation is followed by prompt recovery

In broncho-pneumonia, patient is sicker, and evacuation should be delayed, but there are no hard and fast rules

Decision is based on general impression and careful study of case

As a general rule, thin fluids should be aspirated, thick fluids drained by open operation

Aspiration, usually, does not cure empyema, but is intended to bridge over difficult period and relieves embarrassment from amount of fluid

Intercostal incision is often effectual, but does not provide as good drainage as rib resection, and does not obviate possibility of osteomyelitis of rib

Dr Eggers uses the closed method of drainage as temporary measure in acute cases with extensive exudate to be followed later by rib resection

The reader exhibited a series of lantern slides of X-ray pictures illustrating cases, many of them being chronic empyemata of long standing

Secondary rises of temperature, if other foci can be eliminated, probably means formation of pockets of pus, and here the X-ray is invaluable for diagnosis

In the chronic case, Dr Eggers frequently makes use of X-ray pictures after introduction into the sinus of a solution consisting of Bismuth subcarbonate 20 per cent, acacia 3 per cent in a bland oil, the oil being introduced by gravity, due care being taken to permit exit of air from cavity

J S THOMAS

and that even a man who owns one cow and sells a small quantity of milk only to his neighbors must have his cow tuberculin tested'

---

Publicity of the manner of spreading contagious is commendable, provided the reasons assigned are truthful and well balanced. We are in doubt about the effect of shaking hands on the spread of influenza, but the *Olean Herald*, March 25th, makes an editorial comment on the subject, as follows

"Dr. John Sundwall of the University of Michigan health service says the 'flu' epidemic is due mainly to the friendly handshake

"The infectious organisms of this group of diseases are present in the discharges from the nose and mouth,' he explains and the average man's hands are contaminated with these secretions. A man who has the infection and whose hands are contaminated meets and shakes hands with a friend. Shortly the other's fingers go to his mouth, and the route of transmission is completed'

"It may be futile to urge people to shake hands less, and to stay at home in strict privacy when they have the 'flu' or any other highly contagious disease. There are still many who boast that they 'don't believe in germs,' and the rest are pretty careless. Nothing could suppress the aggressive 'glad hand artist'. But surely it is not too much to ask those suffering either from the 'flu' or from 'common colds,' to wash their hands more frequently. That would help some."

The doctor's statement starts all right by saying that the germs of influenza are in the discharges of the throat and mouth, but he assigns a round-about route of transference of the germs from the sick to the well,—nose of sick person, hands of sick person, hands of well person, nose of well person. Why not tell the public that a far more probable route is that of sneezes, coughs, and loud talking

---

Now and then we find a gem of medical writing that combines truth with high literary merit. The *Hoodstock* (Ulster County) *Weekly*, March 21st, contains a vivid description of the events of a country doctor's busy day which reassures us that the old-fashioned general practitioner still makes his lengthy rounds and in his speedy rush from town to cross roads, is often stopped by decrepit octogenarians and gossiping women who want to know how a distant friend is doing. The doctor writes

"Old Jerry Sparks ahead in the road. He sees us coming and flags us with his cane. On go the brakes. 'Doc, how is Sile getting on?' We hurriedly assure him that Sile is out of danger. Jerry leans on his cane and prepares himself for

a 'real nice visit.' We cut him short and say 'We are in an awful hurry.' We step on the gas. Another two minutes gone forever.

'We stop in to see a little baby desperately sick with broncho-pneumonia. The old grandmother is peeved because we do not prescribe onion poultices to wrists and ankles. Go on, Grandma. Put on the onion poultices. It will not hurt the baby any and will make you feel better.'

---

Dr. Downer writes in this strain for a column or two and ends

"Now we are at the little bridge, and see the little brook sparkling in the moonlight as it hurried on to the sea. That little old ramshackle house over the hill witnessed its tragedy a generation ago. The fair daughter who had gone off to the city, and returned because she had nowhere else to go, was the actress. A hurried call at midnight, on a stormy night, when all nature seemed in revolt. Well, no one has ever known, for the doctor learned early that silence and charity are the greatest of virtues.

"We rambled along and saw the belated moon casting a sheen over the lake. We wondered how many years that picture had been recurring, and if primitive man appreciated its glory. We became analytical, and wondered how many medical men, at that very moment when all the world was in slumber, were abroad on errands of mercy. As the moon waned, the stars brightened, which led us to think of the majesty of the universe. A cloud scudded low, shutting out the distant mountain top. Was it right that a few in this world could live in luxury, while so many lived from hand to mouth? Was it right that a doctor should work day and night, day in and day out, year in and year out? We were commencing to sympathize with ourselves, and really assured ourselves that we were the victims of injustice. In our momentary pessimism we had forgotten family and friends, the wonders of nature, the blue sky, the clouds. We had forgotten the long hard struggle that man had gone through from primitive savagery to his present state of opulence. As we clattered over the loose planked bridge, it woke us from our pessimism.

"Oh, stop sympathizing with yourself," we muttered, "someone must do the hard work. Why not you?" After all would life be worth living unless it be a life of service? You have your work to do, so do it and stop whining. You have your compensations. The fact that you are trying to be a service to your fellows, is your reward. None other is worth while."

This is one of Dr. Downer's weekly health talks. We suggest that he send it to a high-class literary magazine with a national circulation.

# THE DAILY PRESS

New York City has a coordination committee which is composed of 22 representative of the greater social agencies of Greater New York. It was started by "Better Times, Inc.," which is an organization for publishing a magazine called "Better Times." The magazine is promoted and financed by a group of philanthropists, and representatives of social departments of the city government, and the coordination committee is the result of the adoption of the winning plan in a prize contest for the better coordination of the social agencies of the city.

The object of the committee is to coordinate the activities of the various agencies in health, charity, and social uplift. It plans to form a permanent welfare council, and then to disband as a committee. Its budget for the first two years is between 25,000 and 50,000.

The New York *Telegram*, March 28th, contains an editorial on the proposed activities of the Committee, and says:

"No better argument for closer cooperation by all the city's 2,000 public and private welfare agencies could be found than the statistical report just made public by a committee on co-ordination of which Robert W. De Forest is chairman.

It shows that the various groups are distributing about \$80,000,000 a year for philanthropic purposes, of which \$48,550,000, or a little more than sixty per cent, comes from private sources and the rest from city appropriations."

"City funds are disbursed mainly through the Department of Public Works, the Health Department, the Board of Child Welfare, Bellevue and the allied hospitals, parks and playgrounds and certain private institutions."

"With 2,000 accredited agencies in the field there is bound to be some waste through overlapping. It is for the purpose of reducing this to a minimum that the co-ordination committee has undertaken this work. It is a task which should receive the support of the entire community."

The Brooklyn *Eagle*, March 29th, contains a short account of the action of the immigrant authorities in barring unhealthy immigrants among whom were some Irishmen. Their exclusion immediately started trouble according to the account which says:

"On Thursday attorneys appeared before Judge Knox in the Manhattan Federal Court and asked that a governmental investigation be made

of the increasing number of exclusions of the Irish on the grounds these newcomers had weakened hearts.

"Since the outbreak of the World War in 1914 the races of all the war-torn countries have a higher percentage of cardiac weakness," said Dr. Billings last night. "This disease is due to great nervous strain, physical strain and privation, all of which tend to weaken the muscular strength of the heart. The conditions under which these people in the war countries lived have given many valvular troubles.

"A cause of cardiac in the British Isles is the cold. The English and Irish suffer from tonsillitis. This weakens the heart. And both the Irish and the English are noted for their bad teeth. Diseased teeth cause heart disease also.

"He said that the Public Health Service has been able to give 'more thorough medical examinations to incoming immigrants since the reduction of the quotas allowed to enter the country.'"

Stringent ordinances regarding the sale of milk are being adopted throughout the State, most of which follow a standard from which has been suggested by the State Department of Health. The *Batavia News*, March 25, contains an account of the adoption of milk regulations by the City Board of Health, but the article is headed "Complaint About Junk," because a few lines at the end referred to a complaint about an unsightly junk pile. The reference to the milk ordinance is as follows:

"Enforcement of the ordinance that provides that only milk from tuberculin tested cows can be sold in the city of Batavia was taken up at the meeting of the *Board of Health* held at city hall last evening and as a result one dealer who does not handle tuberculin tested milk will be notified that his milk does not comply with the ordinance. The dealer will be given ten days to make arrangements so that his milk will conform with the standard authorized by the ordinance.

"On motion of Dr. Frederick D. Carr it was voted that no milk be accepted for sale in the city of Batavia from any distributor whose total supply does not come from a herd of 100 per cent tuberculin tested cows. No milk shall be accepted whose scoring is not equivalent and does not conform with the regulations of the city of Batavia.

"It was further emphasized by the board that this milk ordinance applies to every dealer, no matter how large or how small his herd may be,

and that even a man who owns one cow and sells a small quantity of milk only to his neighbors must have his cow tuberculin tested"

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL. 25, No 15

NEW YORK, N. Y.

APRIL 24, 1925

## TWENTY-FIVE YEARS' PROGRESS IN MEDICAL EDUCATION IN INTERNAL MEDICINE AND THE MEDICAL SPECIALTIES \*

By SAMUEL W. LAMBERT, M.D.,

NEW YORK CITY

THE successful internist today must be an expert in many branches of medicine to which some of his colleagues devote their entire time, study and research. There are specialists in tuberculosis, in heart disease, in gastroenterology, in syphilis, in pediatrics, in neurology and in other subdivisions of internal medicine. All of these are useful to their patients in exact proportion as they are wise in a knowledge of general diagnosis and pathology, both medical and surgical, and the internist and medical specialist alike to be successful must be skillful in the use of the ophthalmoscope and other instruments of special diagnosis and must be versed in the interpretation of the electro-cardiograph and the radiograph and of the many findings of the instruments and methods of precision in use in the clinical laboratories. From the viewpoint of medical education and of this review, the medical specialties may be considered to include all of the above mentioned groups of diseases of the organs of digestion, of circulation, of the chest and especially neurology, psychology, pediatrics and dermatology and syphilology.

In 1900, medical education in the United States was at the beginning of a great reform. The universities had recently discovered their own medical schools or were ready to absorb into their academic family circles one of the numerous medical outcasts existing in their neighborhoods. Less than a dozen schools among the 160 existing in the country were trying to better their facilities and improve their educational tender to their students. These outstanding exceptions to the general rule were working in isolated attempts without mutual co-operation or conferences with each other. The great majority of the schools were conducted on a discredited proprietary basis largely for the benefit of the professorial proprietors both to increase their personal prestige and for their financial profit.

\* Read at the Meeting of the Council on Medical Education of the American Medical Association in Chicago, March 9, 1925.

In the best schools the entrance requirements were being advanced to the present standard of two years of college work, but a large number of their students were voluntarily offering for entrance a full four-year course with a bachelor degree. A fourth year had already been added to the curriculum which was being crystallized into a thing of fixed hours and of inelastic and limited opportunity for each student, no matter what his mental calibre might be. The new time added to the medical course had been absorbed by the specialties, both medical and surgical, and by an extension of the work in the laboratories of the experimental medical sciences. The methods of teaching of internal medicine had not advanced to a development commensurate with that given in the laboratories or the specialties. Medicine was taught largely by theoretical and clinical lectures to whole classes in an amphitheater and in small groups at the bedside in the wards of a hospital and to a lesser extent in dispensary services. The students had a very limited opportunity to observe and examine the sick patient. Much of the best teaching of the students of these ten or twelve higher grade schools was still being done in 1900 in extra-mural classes of limited numbers by younger teachers who might also be connected with the medical school but who often had no academic standing whatever. These quiz-masters were a holdover from the days of the old proprietary school system in which they formed an important and valuable teaching agent. Conditions of education in all branches of medicine in the one hundred and forty odd poor schools of this period were so chaotic and their work of such miserable quality that it is not worth while to refer to this phase of the subject at all. Even the best characteristics of the proprietary school had disappeared entirely.

In 1900, medical specialties were receiving in these higher class schools greater attention than was being given to the basic subject of Medical

# BOOK REVIEWS

ABT'S PEDIATRICS Vols 4 and 5 By 150 Specialists  
 Edited by ISAAC A. ABT, M.D. Volume 4, containing  
 1271 pages with 271 illustrations (Set to be complete  
 in eight octavo volumes.) Phila. and London, W B  
 Saunders Company, 1924 Cloth, \$10.00 per volume.  
 Sold by subscription

This fourth volume in the series of Pediatrics takes up in detail the Pleura, the Lungs, the Heart, the Mediastinum, the Blood, the Ductless Glands and the Kidneys. Each subject is covered in a complete manner, and as is inevitable from different authors covering different chapters, there is some repetition of subject, but even in the repetition, the subject is presented from a different angle, which makes it valuable. The chapter on the Surgery of the Thorax, by Everts A. Graham, and especially that dealing with empyema, is to be read for its wealth of detail and its conservative attitude.

Electrocardiography in children is more complete and has more supporting statistics than the reviewer has seen elsewhere. This is by Max Seham, who says "In the premature and during the first three months of life, the normal electrocardiogram indicates a right ventricular preponderance. At about the fourth month, R 1 becomes larger than S 1, and from then on the ventricular complex approaches the adult type of curve." And again "The S deflection is the most characteristic and distinctive of the ventricular complex in childhood. In lead I it is relatively and absolutely higher than in any other period of life, and in the other leads it is relatively higher than in the adult."

Transfusion of blood is covered by Lester J. Unger, and as is to be expected the two-way syringe method is recommended. There is, however, some discussion given to the citrate method of transfusion. He says "It is therefore superfluous to attempt a grouping of an infant's blood. One should rather test the blood directly against that of the prospective donor."

Infantilism, with its main divisions, type Lorain and type Brissaud, and their subdivisions, is very fully covered and in an interesting case history manner by Emil Goetsch.

After having picked some of the high spots as above, it occurred to the reviewer that there were a large number of other subjects that could well have been mentioned. In fact, nearly every subject treated can be used for reference. The printing and paper are excellent and the illustrations are frequent and clear, which makes for easy reading. For the physician dealing with children the completed work will be invaluable.

Volume the Fifth of Abt's Pediatrics 865 pages, 375 illustrations includes widely separated subjects, such as Diseases of the Face and Jaws, Orthopedic Surgery, Tuberculosis, Hereditary Syphilis, Erythema Infectiosum, Erythema Nodosum, Bubonic Plague, Actinomycosis, Glandular Fever, Dengue, the Trypanosomiasis, Malta Fever, Kala-azar in Children, Yellow Fever in Children, Malaria, and Infection and Immunity.

The care and treatment of healthy and painful feet is brimful of practical suggestions, some of which the pediatricist can employ with great advantage to his patients. I refer here to the prophylactic foot advice, which should be part of every pediatricist's stock in trade. Then again he should be able to diagnose the abnormalities which will respond to simple treatment and measures, and those which must be referred to the orthopedic surgeon for correction. These matters are made very plain.

The chapter on Hereditary Syphilis deserves special mention for the very good illustrations of the pathology, and the complete handling of treatment.

We cannot close this brief review without favorable comment on the chapters on Erythema Infectiosum, Malaria, and Infection and Immunity.

As the volumes come from the press one after another regard for this work as a practical every-day reference work and working guide rises higher.

ARCHIBALD D. SMITH

OPERATIVE SURGERY Covering the Operative Technique Involved in the Operations of General and Special Surgery By WARREN STONE BICKHAM, M.D., F.A.C.S. Vol 6, completing the set Octavo, 989 pages, 1224 illustrations. General Index to Vols 1 to 6 Octavo, 189 pages. Phila. and London, W B Saunders Co., 1924 Cloth, \$10 per volume. Index volume free. sold by subscription only.

The sixth and final volume of this splendid set is just off the press. It deals in conclusion with operations upon the male genital organs. The approved operations are also described upon the female genito-urinary organs. A final chapter includes operations for deformities and disabilities not considered elsewhere.

As in the other volumes, Dr Bickham has shown the same discriminating care in the selection of illustrations which the really purposeful, as well as the same accurate lucid descriptions of the various operative steps of surgical procedure. It is felt that this set of surgeries will be a monument to the author and that no practitioner who does surgical work should be without this splendid adjunct.

A separately bound index volume for handy reference has been added to the set.

R. H. FOWLER.

COMMON INFECTIONS OF THE FEMALE URETHRA AND CERVIX By FRANK KIDD, M.A., M.Ch., F.R.C.S., and A. MALCOLM SIMPSON, B.A., M.B., D.P.H. With additional chapters by GEORGE T. WESTERN, M.D., and M. S. MAYOU, F.R.C.S. Octavo of 191 pages illustrated. (Oxford Medical Publications.) London, Humphrey Milford, 1924 Cloth, \$2.50.

This small book is worthy of the attention of any doctor who has to deal with this particular branch of medicine.

There can be no doubt of what the authors wish to convey, as the style of the book is simple, clear and indeed forceful when dealing with controvertible matter.

Many old beliefs that are taught today by some of the leading gynecologists are ruthlessly destroyed, and even though the conclusions of the authors may not be taken *in toto*, yet the challenge remains and considerable work and painstaking observations must be made in order to refute the authors' conclusions.

Take but on instance—infection of the Bartholin gland—the authors state that 38 per cent of the infections of this gland are non-gonorrheal. This conclusion is based not alone on observation but on thorough laboratory investigation as well.

The book is replete with such instances of old ideas destroyed. In treatment the authors again offer methods radically different to much that is taught.

In conclusion the reviewer feels that however much the reader may differ with the authors, they cannot refute the authors' conclusions unless backed by modern laboratory aid and a prolonged study of the subject in question.

## TWENTY-FIVE YEARS' PROGRESS IN MEDICAL EDUCATION IN INTERNAL MEDICINE AND THE MEDICAL SPECIALTIES\*

By SAMUEL W. LAMBERT, M.D.,

NEW YORK CITY

THE successful internist today must be an expert in many branches of medicine to which some of his colleagues devote their entire time, study and research. There are specialists in tuberculosis, in heart disease, in gastro-enterology, in syphilis, in pediatrics, in neurology and in other subdivisions of internal medicine. All of these are useful to their patients in exact proportion as they are wise in a knowledge of general diagnosis and pathology both medical and surgical, and the internist and medical specialist alike to be successful must be skillful in the use of the ophthalmoscope and other instruments of special diagnosis and must be versed in the interpretation of the electro-cardiograph and the radiograph and of the many findings of the instruments and methods of precision in use in the clinical laboratories. From the viewpoint of medical education and of this review, the medical specialties may be considered to include all of the above mentioned groups of diseases of the organs of digestion, of circulation, of the chest and especially neurology, psychology, pediatrics and dermatology and syphilology.

In 1900, medical education in the United States was at the beginning of a great reform. The universities had recently discovered their own medical schools or were ready to absorb into their academic family circles one of the numerous medical outcasts existing in their neighborhoods. Less than a dozen schools among the 160 existing in the country were trying to better their facilities and improve their educational tender to their students. These outstanding exceptions to the general rule were working in isolated attempts without mutual co-operation or conferences with each other. The great majority of the schools were conducted on a discredited proprietary basis largely for the benefit of the professorial proprietors both to increase their personal prestige and for their financial profit.

In the best schools the entrance requirements were being advanced to the present standard of two years of college work, but a large number of their students were voluntarily offering for entrance a full four-year course with a bachelor degree. A fourth year had already been added to the curriculum which was being crystallized into a thing of fixed hours and of inelastic and limited opportunity for each student, no matter what his mental calibre might be. The new time added to the medical course had been absorbed by the specialties, both medical and surgical, and by an extension of the work in the laboratories of the experimental medical sciences. The methods of teaching of internal medicine had not advanced to a development commensurate with that given in the laboratories or the specialties. Medicine was taught largely by theoretical and clinical lectures to whole classes in an amphitheater and in small groups at the bedside in the wards of a hospital and to a lesser extent in dispensary services. The students had a very limited opportunity to observe and examine the sick patient. Much of the best teaching of the students of these ten or twelve higher grade schools was still being done in 1900 in extra-mural classes of limited numbers by younger teachers who might also be connected with the medical school but who often had no academic standing whatever. These quiz-masters were a holdover from the days of the old proprietary school system in which they formed an important and valuable teaching agent. Conditions of education in all branches of medicine in the one hundred and forty odd poor schools of this period were so chaotic and their work of such miserable quality that it is not worth while to refer to this phase of the subject at all. Even the best characteristics of the proprietary school had disappeared entirely.

In 1900 medical specialties were receiving in these higher class schools greater attention than was being given to the basic subject of Medical

**ABT'S PEDIATRICS** Vols 4 and 5 By 150 Specialists  
 Edited by ISAAC A. ABT, M.D. Volume 4, containing 1271 pages with 271 illustrations (Set to be complete in eight octavo volumes) Phila. and London, W. B. Saunders Company, 1924 Cloth, \$10.00 per volume. Sold by subscription

This fourth volume in the series of Pediatrics takes up in detail the Pleura, the Lungs, the Heart, the Mediastinum, the Blood, the Ductless Glands and the Kidneys. Each subject is covered in a complete manner, and as is inevitable from different authors covering different chapters, there is some repetition of subject, but even in the repetition, the subject is presented from a different angle, which makes it valuable. The chapter on the Surgery of the Thorax, by Everts A. Graham, and especially that dealing with empyema, is to be read for its wealth of detail and its conservative attitude.

Electrocardiography in children is more complete and has more supporting statistics than the reviewer has seen elsewhere. This is by Max Seham, who says "In the premature and during the first three months of life, the normal electrocardiogram indicates a right ventricular preponderance. At about the fourth month, R 1 becomes larger than S 1, and from then on the ventricular complex approaches the adult type of curve." And again "The S deflection is the most characteristic and distinctive of the ventricular complex in childhood. In lead I it is relatively and absolutely higher than in any other period of life, and in the other leads it is relatively higher than in the adult."

Transfusion of blood is covered by Lester J. Unger, and as is to be expected the two-way syringe method is recommended. There is, however, some discussion given to the citrate method of transfusion. He says "It is therefore superfluous to attempt a grouping of an infant's blood. One should rather test the blood directly against that of the prospective donor."

Infantilism, with its main divisions, type Lorain and type Brissaud, and their subdivisions, is very fully covered and in an interesting case history manner by Emil Goetsch.

After having picked some of the high spots as above, it occurred to the reviewer that there were a large number of other subjects that could well have been mentioned. In fact, nearly every subject treated can be used for reference. The printing and paper are excellent and the illustrations are frequent and clear, which makes for easy reading. G. W. P.

made for the Carnegie Foundation for the Advancement of Teaching and published in 1910. This report presented in great detail the shortcomings of the individual schools. It was a great help to every school which was in earnest to better the instruction given and to improve its own status. This report proved a moral force to help the Council in its work. The results of the work of the Council have been accomplished without any authority to enforce its suggestions, but entirely through its strength of organization and its power to influence public opinion and medical opinion and to persuade legislation in the states. The Council stands today as the representative body of physicians in their efforts to improve themselves.

The Association of Medical Colleges has undertaken to work out in detail the desires of its component schools to improve education. It also has become a great power to bring about reform under the leadership of the best educators in the profession. Its work is done as the representative of the schools rather than as that of the general profession.

The influence of the state licensing boards and the medical practice laws under which they act is of quite a different nature. It represents the state control of the professional education in medicine. The result on the whole curriculum of the medical schools has been a standardizing of a minimum requirement which any school may exceed but which no school may fail to meet without risking the exclusion of all its graduates from the licensing examination of the particular state whose law has been transgressed. Any large state, such as New York or Pennsylvania, influences medical education not only at home but in every other state, and the individual school to be accepted universally, must equal or exceed the maximum requirements of every state. As a matter of fact and in practice, the state departments have viewed minor infringements with broad toleration, and the best schools have always led and demanded of their students more than the requirements of any state law. The result of such control by law has raised the general standard of education without question, but it has not been entirely an unmixed benefit. The rigid and inelastic curriculum of today is the result of these laws which unite in demanding not only that a fixed number of hours be allotted to each subject but also that the total 3,600 or 4,000 hours of instruction be spread over four calendar years in four periods of eight months each. Some of these laws demand the addition of unusual subjects for instruction, which may be criticized in good faith as unwise or unnecessary. The state laws, therefore, prescribe not only a fixed number of hours of instruction, but also compel a fixed number of months of vacation each year for every student of medicine.

The result often is, however, that the more eager students undertake clinical work in hospitals during vacation, although they receive no credit for it either by state or university.

Under the influence of the forces just enumerated the present conditions in medical education have developed. The result is neither uniform nor finished. It probably never will be finished for medicine is a growing science and progress will be more sure and steady if the teaching of it never becomes uniform. Internal medicine has regained its merited place of chief prominence in the curriculum of most schools. This has been done either by devoting more hours than the legal requirement to it or by reducing the hours allotted to the specialties to the bare demands of the law. The system of clinical clerks has been introduced in the higher grade schools. The mere admission of students to hospital wards is not sufficient, it is essential that these students must be made to feel the responsibility of their privilege. This can be accomplished only by making their work a part of the permanent record of the hospital. Extra-mural courses as formerly given in internal medicine and in specialties have been practically abolished. The energy which formerly found expression in this way is now devoted to post graduate work. The hospitals have been largely reorganized so that an old fashioned rotating service is exceptional. The plan first put into practice in internal medicine by Osler at Johns Hopkins, of a pyramided staff consisting of a director, associates, assistants, residents, internes, and medical students, is generally recognized as the best that has been devised up to the present time even by those teachers who have not yet adopted it. The securing of an affiliated hospital is still the chief element of success in the organization of the medical department of every school. The education of the hospital trustee is still as important as it was when this question was discussed in the meeting of this Council ten years ago, in 1915. The correlation of internal medicine with previous training in work of the laboratory, is today one of the prominent problems of the medical educator. The report of the Council for 1923 calls attention to this question. It is recognized as of immediate importance, and though difficult of solution, it is the subject of study in every important school. The correlation of the subjects of a medical curriculum is usually understood to mean the proper sequence in which to present the numerous subjects to the students. Much worry has been caused to many teachers by the fear that the medical student who begins a new subject will not be properly instructed in those subjects necessary for him to understand his graded advance in the successive steps of his education. Such a correlation is important enough, but there is another phase to this interrelation of the subject matter of a medical educa-

Practice itself Neurology was presented fully, both as to clinical diagnosis and, so far as it was known, to the anatomical localization of the functional action of the nervous system Pediatrics, which embraces all that internal medicine does and in addition includes the special problems of diet for children and the greater incidence of contagious diseases in early life, had become a specialty of major importance Under the lead of such masters as Rotch in Boston, and of Jacobi and Holt in New York, the diseases and care of children were being impressed on the students of medicine in many schools even as early as 1900 The third medical specialty of dermatology and syphilology had not yet grown into its present day importance which resulted from the discoveries in therapeutics of Ehrlich and his followers In 1900, pediatrics and neurology each occupied as much time in the curriculum as did all the rest of internal medicine together At the beginning of the twentieth century internal medicine was a comparatively neglected subject This was due to the addition and growth of the newly discovered sciences of bacteriology and bio-chemistry, and of the operative branches of surgery and the surgical specialties

The one great outstanding event in medical education of the late 19th century was the founding of a medical school in Baltimore owning a large endowment, its own hospital, with no inherited prejudices of a proprietary nature, especially with no traditions as to hospital prerogatives The most important factor in the history of the teaching of internal medicine was the selection for the single head of this medical clinic of a remarkable man—William Osler It is a fact to note that Johns Hopkins built and equipped and opened its hospital several years before any medical students were admitted to the school This order of development was the same which signalized the origin of medical education in America in the early 18th century, when Samuel Bard, just returned from Edinburgh, founded the New York Hospital before he induced King's College to admit medical students to be taught in college and hospital The same procedure was true of the beginnings of the Pennsylvania Hospital and the medical department of the University of Philadelphia under the leadership of Thos Bond and John Morgan Osler re-established the English method of clinical clerks and surgical dressers in the wards of Johns Hopkins This real reform of clinical teaching in internal medicine was adopted slowly by other schools largely because of the difficulty of persuading the trustees of the available hospitals that such a plan was not only a duty but a distinct advantage to their own institutions It is not yet a universal method of instruction, although it ought to be at least until the addition of a fifth interne year to the curriculum, as

more recently proposed, has become an accomplished fact The influence of William Osler on the teaching of internal medicine was not limited to Baltimore Just before he left this country he called together twenty-four younger teachers from the four greater cities in the East and formed a "club" whose objective should be to visit each university represented in turn for the express purpose of studying not only the new research which was under way and unpublished, but also the methods of teaching in use in the different schools Through this medium the ward classes and laboratory methods of the University of Pennsylvania, the methods introduced at Johns Hopkins by Osler and his colleagues already referred to, the amplified system of using dispensary services especially in teaching therapeutics as distinguished from the use of hospital wards which had been forced on the schools of New York by the stupid stubbornness of the trustees of the metropolitan hospitals, and the case teaching methods and medical-pathological conferences as developed at Harvard under the leadership of Richard Cabot and Wright, all these became more universally known and were adopted by other schools The original members of this interurban clinical club and those subsequently elected have shifted their university connection and have carried the spirit and enthusiasm of Osler to Connecticut, Indiana, Michigan, Minnesota, Missouri, and other centers of medical education

The leaders in other branches of medical science were as keen as those working in internal medicine and the general tendency in all the high grade schools was for improvement The modern reform in medical education began within the profession itself It was in 1900 also that organized medicine began to notice medical education and the Journal of the American Medical Association to collect statistics on the education of medical students Under the initiative of this organization the Council on Medical Education and Hospitals began its epoch making work in 1904 During the past 21 years this Council, under its able chairman, has been a most potent force to elevate the standards of and to influence medical education favorably Its rating of medical schools, the intensive discussions on standards and on the school curriculum at its meetings, its annual reports on every phase of medical practice, its assistance and advice given to weaker schools, have accomplished much to improve education in every department of medicine Its chief credit lies in the reduction of the number of schools from 160 to 80 by the elimination of the hopelessly weak Of the eighty schools now left, only twelve lack universal recognition in every state in the Union

The results of the inspections of the Council and those of an independent investigation were embodied by Mr Abraham Flexner in a report

made for the Carnegie Foundation for the Advancement of Teaching and published in 1910. This report presented in great detail the shortcomings of the individual schools. It was a great help to every school which was in earnest to better the instruction given and to improve its own status. This report proved a moral force to help the Council in its work. The results of the work of the Council have been accomplished without any authority to enforce its suggestions, but entirely through its strength of organization and its power to influence public opinion and medical opinion and to persuade legislation in the states. The Council stands today as the representative body of physicians in their efforts to improve themselves.

The Association of Medical Colleges has undertaken to work out in detail the desires of its component schools to improve education. It also has become a great power to bring about reform under the leadership of the best educators in the profession. Its work is done as the representative of the schools rather than as that of the general profession.

The influence of the state licensing boards and the medical practice laws under which they act is of quite a different nature. It represents the state control of the professional education in medicine. The result on the whole curriculum of the medical schools has been a standardizing of a minimum requirement which any school may exceed but which no school may fail to meet without risking the exclusion of all its graduates from the licensing examination of the particular state whose law has been transgressed. Any large state, such as New York or Pennsylvania, influences medical education not only at home but in every other state, and the individual school to be accepted universally, must equal or exceed the maximum requirements of every state. As a matter of fact and in practice, the state departments have viewed minor infringements with broad toleration, and the best schools have always led and demanded of their students more than the requirements of any state law. The result of such control by law has raised the general standard of education without question, but it has not been entirely an unmixed benefit. The rigid and inflexible curriculum of today is the result of these laws which unite in demanding not only that a fixed number of hours be allotted to each subject but also that the total 3,600 or 4,000 hours of instruction be spread over four calendar years in four periods of eight months each. Some of these laws demand the addition of unusual subjects for instruction, which may be criticized in good faith as unwise or unnecessary. The state laws, therefore, prescribe not only a fixed number of hours of instruction, but also compel a fixed number of months of vacation each year for every student of medicine.

The result often is, however, that the more eager students undertake clinical work in hospitals during vacation, although they receive no credit for it either by state or university.

Under the influence of the forces just enumerated the present conditions in medical education have developed. The result is neither uniform nor finished. It probably never will be finished for medicine is a growing science and progress will be more sure and steady if the teaching of it never becomes uniform. Internal medicine has regained its merited place of chief prominence in the curriculum of most schools. This has been done either by devoting more hours than the legal requirement to it or by reducing the hours allotted to the specialties to the bare demands of the law. The system of clinical clerks has been introduced in the higher grade schools. The mere admission of students to hospital wards is not sufficient, it is essential that these students must be made to feel the responsibility of their privilege. This can be accomplished only by making their work a part of the permanent record of the hospital. Extra-mural courses as formerly given in internal medicine and in specialties have been practically abolished. The energy which formerly found expression in this way is now devoted to post graduate work. The hospitals have been largely reorganized so that an old fashioned rotating service is exceptional. The plan first put into practice in internal medicine by Osler at Johns Hopkins, of a pyramided staff consisting of a director, associates, assistants, residents, internes, and medical students, is generally recognized as the best that has been devised up to the present time even by those teachers who have not yet adopted it. The securing of an affiliated hospital is still the chief element of success in the organization of the medical department of every school. The education of the hospital trustee is still as important as it was when this question was discussed in the meeting of this Council ten years ago, in 1915. The correlation of internal medicine with previous training in work of the laboratory, is today one of the prominent problems of the medical educator. The report of the Council for 1923 calls attention to this question. It is recognized as of immediate importance, and though difficult of solution, it is the subject of study in every important school. The correlation of the subjects of a medical curriculum is usually understood to mean the proper sequence in which to present the numerous subjects to the students. Much worry has been caused to many teachers by the fear that the medical student who begins a new subject will not be properly instructed in those subjects necessary for him to understand his graded advance in the successive steps of his education. Such a correlation is important enough, but there is another phase to this interrelation of the subject matter of a medical educa-

Practice itself Neurology was presented fully, both as to clinical diagnosis and, so far as it was known, to the anatomical localization of the functional action of the nervous system Pediatrics, which embraces all that internal medicine does and in addition includes the special problems of diet for children and the greater incidence of contagious diseases in early life, had become a specialty of major importance Under the lead of such masters as Rotch in Boston, and of Jacoby and Holt in New York, the diseases and care of children were being impressed on the students of medicine in many schools even as early as 1900 The third medical specialty of dermatology and syphilology had not yet grown into its present day importance which resulted from the discoveries in therapeutics of Ehrlich and his followers In 1900, pediatrics and neurology each occupied as much time in the curriculum as did all the rest of internal medicine together At the beginning of the twentieth century internal medicine was a comparatively neglected subject This was due to the addition and growth of the newly discovered sciences of bacteriology and bio-chemistry, and of the operative branches of surgery and the surgical specialties

The one great outstanding event in medical education of the late 19th century was the founding of a medical school in Baltimore owning a large endowment, its own hospital, with no inherited prejudices of a proprietary nature, especially with no traditions as to hospital prerogatives The most important factor in the history of the teaching of internal medicine was the selection for the single head of this medical clinic of a remarkable man—William Osler It is a fact to note that Johns Hopkins built and equipped and opened its hospital several years before any medical students were admitted to the school This order of development was the same which signalized the origin of medical education in America in the early 18th century, when Samuel Bard, just returned from Edinburgh founded the New York Hospital before he induced King's College to admit medical students to be taught in college and hospital The same procedure was true of the beginnings of the Pennsylvania Hospital and the medical department of the University of Philadelphia under the leadership of Thos Bond and John Morgan Osler re-established the English method of clinical clerks and surgical dressers in the wards of Johns Hopkins This real reform of clinical teaching in internal medicine was adopted slowly by other schools largely because of the difficulty of persuading the trustees of the available hospitals that such a plan was not only a duty but a distinct advantage to their own institutions It is not yet a universal method of instruction, although it ought to be at least until the addition of a fifth interne year to the curriculum, as

more recently proposed, has become an accomplished fact The influence of William Osler on the teaching of internal medicine was not limited to Baltimore Just before he left this country he called together twenty-four younger teachers from the four greater cities in the East and formed a "club" whose objective should be to visit each university represented in turn for the express purpose of studying not only the new research which was under way and unpublished, but also the methods of teaching in use in the different schools Through this medium the ward classes and laboratory methods of the University of Pennsylvania, the methods introduced at Johns Hopkins by Osler and his colleagues already referred to, the amplified system of using dispensary services especially in teaching therapeutics as distinguished from the use of hospital wards which had been forced on the schools of New York by the stupid stubbornness of the trustees of the metropolitan hospitals, and the case teaching methods and medical-pathological conferences as developed at Harvard under the leadership of Richard Cabot and Wright, all these became more universally known and were adopted by other schools The original members of this interurban clinical club and those subsequently elected have shifted their university connection and have carried the spirit and enthusiasm of Osler to Connecticut, Indiana, Michigan, Minnesota, Missouri, and other centers of medical education

The leaders in other branches of medical science were as keen as those working in internal medicine and the general tendency in all the high grade schools was for improvement The modern reform in medical education began within the profession itself It was in 1900 also that organized medicine began to notice medical education and the Journal of the American Medical Association to collect statistics on the education of medical students Under the initiative of this organization the Council on Medical Education and Hospitals began its epoch making work in 1904 During the past 21 years this Council, under its able chairman, has been a most potent force to elevate the standards of and to influence medical education favorably Its rating of medical schools, the intensive discussions on standards and on the school curriculum at its meetings, its annual reports on every phase of medical practice, its assistance and advice given to weaker schools, have accomplished much to improve education in every department of medicine Its chief credit lies in the reduction of the number of schools from 160 to 80 by the elimination of the hopelessly weak Of the eighty schools now left, only twelve lack universal recognition in every state in the Union

The results of the inspections of the Council and those of an independent investigation were embodied by Mr Abraham Flexner in a report

made for the Carnegie Foundation for the Advancement of Teaching and published in 1910. This report presented in great detail the shortcomings of the individual schools. It was a great help to every school which was in earnest to better the instruction given and to improve its own status. This report proved a moral force to help the Council in its work. The results of the work of the Council have been accomplished without any authority to enforce its suggestions, but entirely through its strength of organization and its power to influence public opinion and medical opinion and to persuade legislation in the states. The Council stands today as the representative body of physicians in their efforts to improve themselves.

The Association of Medical Colleges has undertaken to work out in detail the desires of its component schools to improve education. It also has become a great power to bring about reform under the leadership of the best educators in the profession. Its work is done as the representative of the schools rather than as that of the general profession.

The influence of the state licensing boards and the medical practice laws under which they act is of quite a different nature. It represents the state control of the professional education in medicine. The result on the whole curriculum of the medical schools has been a standardizing of a minimum requirement which any school may exceed but which no school may fail to meet without risking the exclusion of all its graduates from the licensing examination of the particular state whose law has been transgressed. Any large state, such as New York or Pennsylvania, influences medical education not only at home but in every other state, and the individual school to be accepted universally, must equal or exceed the maximum requirements of every state. As a matter of fact and in practice, the state departments have viewed minor infringements with broad toleration, and the best schools have always led and demanded of their students more than the requirements of any state law. The result of such control by law has raised the general standard of education without question, but it has not been entirely an unmixed benefit. The rigid and inelastic curriculum of today is the result of these laws which unite in demanding not only that a fixed number of hours be allotted to each subject but also that the total 3,600 or 4,000 hours of instruction be spread over four calendar years in four periods of eight months each. Some of these laws demand the addition of unusual subjects for instruction, which may be criticized in good faith as unwise or unnecessary. The state laws, therefore, prescribe not only a fixed number of hours of instruction, but also compel a fixed number of months of vacation each year for every student of medicine.

The result often is, however, that the more eager students undertake clinical work in hospitals during vacation, although they receive no credit for it either by state or university.

Under the influence of the forces just enumerated the present conditions in medical education have developed. The result is neither uniform nor finished. It probably never will be finished for medicine is a growing science and progress will be more sure and steady if the teaching of it never becomes uniform. Internal medicine has regained its merited place of chief prominence in the curriculum of most schools. This has been done either by devoting more hours than the legal requirement to it or by reducing the hours allotted to the specialties to the bare demands of the law. The system of clinical clerks has been introduced in the higher grade schools. The mere admission of students to hospital wards is not sufficient, it is essential that these students must be made to feel the responsibility of their privilege. This can be accomplished only by making their work a part of the permanent record of the hospital. Extra-mural courses as formerly given in internal medicine and in specialties have been practically abolished. The energy which formerly found expression in this way is now devoted to post graduate work. The hospitals have been largely reorganized so that an old fashioned rotating service is exceptional. The plan first put into practice in internal medicine by Osler at Johns Hopkins, of a pyramided staff consisting of a director, associates, assistants, residents, internes, and medical students, is generally recognized as the best that has been devised up to the present time even by those teachers who have not yet adopted it. The securing of an affiliated hospital is still the chief element of success in the organization of the medical department of every school. The education of the hospital trustee is still as important as it was when this question was discussed in the meeting of this Council ten years ago, in 1915. The correlation of internal medicine with previous training in work of the laboratory, is today one of the prominent problems of the medical educator. The report of the Council for 1923 calls attention to this question. It is recognized as of immediate importance, and though difficult of solution, it is the subject of study in every important school. The correlation of the subjects of a medical curriculum is usually understood to mean the proper sequence in which to present the numerous subjects to the students. Much worry has been caused to many teachers by the fear that the medical student who begins a new subject will not be properly instructed in those subjects necessary for him to understand his graded advance in the successive steps of his education. Such a correlation is important enough, but there is another phase to this interrelation of the subject matter of a medical educa-

tion It is most important that a student may discover early in his career that the facts of anatomy, physiology and bacteriology are of the greatest use in surgery, and that his laboratory experiences in physiology, bacteriology, chemistry, pathology and pharmacology are of vital importance to the proper understanding of internal medicine and the medical specialties This is not merely a question of the sequence of the subjects of a curriculum There is a correlation of much greater significance in this matter It is necessary that the younger instructor in medicine and surgery has a keen interest in the details of the underlying subjects taught in the laboratories of his institution The appointment to a teaching position in internal medicine should presuppose a previous or contemporary service as an instructor in one or more of the laboratory subjects of physiology, pharmacology, chemistry or bacteriology, and a similar appointment in the department of surgery should lie through a service in anatomy, bacteriology and pathology, or even in all three

Ten schools, in California (3), Illinois (4), Minnesota (1), Michigan (1), and Wisconsin (1), have added a fifth year, to be spent by the student as an interne in an approved hospital Such an arrangement demands from the school a strict supervision to avoid the pitfalls incident to adding extra-mural work to the medical curriculum The majority of graduates voluntarily take a longer internship than one year if they can secure such a one, and most schools have not felt it desirable to adopt this innovation, although eleven states make the same demand as an essential qualification for the license to practice It is an interesting anomaly that only two states (Illinois and Michigan) are in accord with their own schools in making the demand The fifth interne year seems a logical sequence to the trend of medical education in internal medicine and general surgery during the past decade But an ideal scheme by which any school can control the personnel of a sufficient number of hospitals to place all its graduates seems too distant a goal to be reached in any measurable period of time The present advantage of the fifth year seems to be limited to an approval by his school of the hospitals to which a prospective graduate may go The fifth year is an advance, however, and properly administered will lead to greater usefulness in education of a larger number of hospitals than is now the case and will improve the opportunities for teaching in clinical work in the major subjects of medicine, surgery and pediatrics, and in some specialties as well, for the students of the third and fourth year classes

Whether a school adopts a five-year curriculum on some development of this innovation, or remains on a four-year basis and the well tried system of clinical clerks, it will be the number of hospital beds in general medicine and in sur-

gery under the control of the school which will determine the number of students that can be taken care of in each class and, therefore, the enrollment of medical students in that university There is an educational unit which is somewhere between 100 and 125 students which can be given an acceptable education with an equipment in hospital beds and personnel of a given size This minimum to teach 100 students in a class has been placed by the Council on Medical Education as six teachers for each subject, whether general or special, whether laboratory or clinical, and not less than 200 patients in hospital beds who can be utilized for clinical teaching If any university wishes to exceed this educational unit it should duplicate its hospital facilities and also its personnel in both laboratory and clinical subjects The hospital cannot be used for a second unit without detriment to the welfare of the patients, but the laboratories may well be so employed if the personnel be doubled

Medical education in the United States has reached a development during 25 years of which the profession may be proud The main objective as outlined by the general profession and directed by the Council on Medical Education has been the same as that demanded by the general public and enforced by the state legislatures It was that licensed physicians should have a careful training in the causation, diagnosis, therapeutics and pathology of general diseases, in pediatrics and in obstetrics and that an opportunity should exist for graduates to perfect themselves in surgery and the specialties Such a result has become more nearly a fact than has been the case during any time in the past The advance of the past 25 years has been the greatest of any previous period of twice its length

The course of progress has not been without disturbing factors during the past quarter century The World's War proved to be no help Even before April, 1917, there was a tendency for the teachers in American schools to wander off to Europe to secure personal experience of the unusual happenings in medicine and surgery which were going on in the world It was the sudden demand of an American Army of some 4,000,000 men to be supplied with a medical corps and the Federal draft law that so nearly wrecked medical education for the time being It is impossible for a young man to do full time service in two specialties The training of a soldier and the training of a physician are each full-time jobs The attempt to require both of the students of medicine was the stumbling block which caused much worry both in a bureau of the office of the Surgeon General and in the offices of the Deans of many medical schools It lasted only a short two years, after which medical education attempted to return to a quieter road to progress But

the war had changed a large number of the younger medical men. Two years in the Army or Navy had proved insufficient to teach these physicians a true appreciation of service discipline. They did not bring back from their military work any of the good points of the Army or Navy Medical Corps. But somewhere between their resignation from their schools and their discharge from the Army or Navy they had acquired the very bad habit of shirking responsibility and in the slang of the day of "passing the buck." Such a habit of thought and action has no place in the medical profession.

The second event of note is the much praised establishment of the full-time professorship. The claims set forth in support of this American experiment in medical education are so well known that a statement in great detail seems superfluous. It has been described by its most important advocate "as a protection and not as a restriction, not as an abridgement of liberty but as a permanent and effective protection against distraction in the interest of conditions desired by the scientist for the pursuit of his own highest ends." It is customary to compare the ideal full-time professor of internal medicine with the professor of Greek in the same university. In medical education this full-time idea is of special interest to the teaching of internal medicine which is the first department in every school to be drafted in this so-called reform. I admit that I have been opposed to the full-time idea from its very beginning. I believed that it would tend to diminish attention to the hospital wards rather than the reverse, that it would create a habit of thought that the sick were objects for research rather than subjects for cure, that it would limit the experience of the younger men trained in the isolation of a full-time clinic and that the ultimate product, the recent graduate, would acquire a very restricted view of medical diagnosis and therapeutic measures. It is no longer my duty to be a part of the organized education of medical men but as medical director of a hospital service I have an opportunity to study the results of the education of many schools by examination for hospital internships and by contact with the internes themselves. I have seen no reason to change my mind concerning the rigid full-time idea. From two sources I have received the opinion of the full-time professor concerning the undesirability of sharing the instruction of his students with any colleague of equal authority in clinical medicine. One of them has written: "The custom of 'giving instruction in three clinics differing considerably in their character leads to diffuseness, a lack of uniformity and widely varying

points of view, which tend to confuse the average student." This full-time professor at least does not possess a correct idea of clinical medicine. A correct diagnosis can often be reached only by sifting the varying opinions that will be drawn from a collection of clinical facts which are often necessarily incomplete. The sooner that a medical student awakes to the fact that a clinical diagnosis is only an hypothesis upon which to formulate treatment and which is subject to constant change as new facts are discovered so much the sooner will he be started on a successful career. I have observed that the full-time professor of medicine takes the same vacation as does his full-time colleague in the department of Greek, and that both are likely to have the same limited viewpoint and lack of touch with the economics and social needs of the community. This is often true in spite of the fact that one is ruler over a dead language which will remain in *statu quo* until the professor returns to his desk, while the other is in charge of a very living organism, the hospital, which works without vacation seven days in the week and 365 days in the year. I believe the future development of medical education will not be along the line of the full-time clinic with its long vacation, its cloister isolation and its ex-cathedra teaching. Backed as it is by millions this fallacious system has been able to buy its way into many places of prominence. It is a hectic educational disease which allowed to run to a logical conclusion will ruin the finances of any medical school now existing. Medical education will recover from it and will probably be uninjured by the experience.

I have recently examined for internships thirty high-grade students from ten schools, ranging from Massachusetts to South Carolina and from New York to Ohio. The outstanding characteristics of these young men was a very incompetent understanding of therapeutics. I was advised to use tartar emetic as a cathartic and aspidium for any intestinal parasite from hook worm to pin worm. Their advice in regard to digitalis was pharmacological and not clinical. Modern medical teaching neglects the essential point of instructing students how to mix and administer the simplest *materia medica* in the proper vehicle of brains. When it came to diagnosis only one of these thirty men used his ear applied to the chest in addition to his stethoscope. All of them gave the impression that they had not been taught to use their five senses, but would prefer to work with fifty-five instruments of more or less inaccurate precision. The modern education of the physician lays undue stress on the laboratory in diagnosis and neglects the study of the symptomatology of the onset and the

tion It is most important that a student may discover early in his career that the facts of anatomy, physiology and bacteriology are of the greatest use in surgery, and that his laboratory experiences in physiology, bacteriology, chemistry, pathology and pharmacology are of vital importance to the proper understanding of internal medicine and the medical specialties This is not merely a question of the sequence of the subjects of a curriculum There is a correlation of much greater significance in this matter It is necessary that the younger instructor in medicine and surgery has a keen interest in the details of the underlying subjects taught in the laboratories of his institution The appointment to a teaching position in internal medicine should presuppose a previous or contemporary service as an instructor in one or more of the laboratory subjects of physiology, pharmacology, chemistry or bacteriology, and a similar appointment in the department of surgery should lie through a service in anatomy, bacteriology and pathology, or even in all three

Ten schools, in California (3), Illinois (4) Minnesota (1), Michigan (1), and Wisconsin (1), have added a fifth year, to be spent by the student as an interne in an approved hospital Such an arrangement demands from the school a strict supervision to avoid the pitfalls incident to adding extra-mural work to the medical curriculum The majority of graduates voluntarily take a longer internship than one year if they can secure such a one, and most schools have not felt it desirable to adopt this innovation, although eleven states make the same demand as an essential qualification for the license to practice It is an interesting anomaly that only two states (Illinois and Michigan) are in accord with their own schools in making the demand The fifth interne year seems a logical sequence to the trend of medical education in internal medicine and general surgery during the past decade But an ideal scheme by which any school can control the personnel of a sufficient number of hospitals to place all its graduates seems too distant a goal to be reached in any measurable period of time The present advantage of the fifth year seems to be limited to an approval by his school of the hospitals to which a prospective graduate may go The fifth year is an advance, however, and properly administered will lead to greater usefulness in education of a larger number of hospitals than is now the case and will improve the opportunities for teaching in clinical work in the major subjects of medicine, surgery and pediatrics, and in some specialties as well, for the students of the third and fourth year classes

Whether a school adopts a five-year curriculum on some development of this innovation, or remains on a four-year basis and the well tried system of clinical clerks, it will be the number of hospital beds in general medicine and in sur-

gery under the control of the school which will determine the number of students that can be taken care of in each class and, therefore, the enrollment of medical students in that university There is an educational unit which is somewhere between 100 and 125 students which can be given an acceptable education with an equipment in hospital beds and personnel of a given size. This minimum to teach 100 students in a class has been placed by the Council on Medical Education as six teachers for each subject, whether general or special, whether laboratory or clinical, and not less than 200 patients in hospital beds who can be utilized for clinical teaching If any university wishes to exceed this educational unit it should duplicate its hospital facilities and also its personnel in both laboratory and clinical subjects The hospital cannot be used for a second unit without detriment to the welfare of the patients, but the laboratories may well be so employed if the personnel be doubled

Medical education in the United States has reached a development during 25 years of which the profession may be proud The main objective as outlined by the general profession and directed by the Council on Medical Education has been the same as that demanded by the general public and enforced by the state legislatures It was that licensed physicians should have a careful training in the causation, diagnosis, therapeutics and pathology of general diseases, in pediatrics and in obstetrics and that an opportunity should exist for graduates to perfect themselves in surgery and the specialties Such a result has become more nearly a fact than has been the case during any time in the past The advance of the past 25 years has been the greatest of any previous period of twice its length

The course of progress has not been without disturbing factors during the past quarter century The World's War proved to be no help Even before April, 1917, there was a tendency for the teachers in American schools to wander off to Europe to secure personal experience of the unusual happenings in medicine and surgery which were going on in the world It was the sudden demand of an American Army of some 4,000,000 men to be supplied with a medical corps and the Federal draft law that so nearly wrecked medical education for the time being It is impossible for a young man to do full time service in two specialties The training of a soldier and the training of a physician are each full-time jobs The attempt to require both of the students of medicine was the stumbling block which caused much worry both in a bureau of the office of the Surgeon General and in the offices of the Deans of many medical schools It lasted only a short two years, after which medical education attempted to return to a quieter road to progress But

straints, it went through the world war on the "thou shalt nots" of its President. This country is ruled by and loves its prohibitions, whether it be the prohibition of cigarettes or the prohibition of medical education, which denies to any student, however capable or diligent, the privilege of learning his profession any faster than is possible for the laziest and dullest student who can scrape through in four years, the minimum requirements of the university and licensing board of his State.

It is customary to condemn *in toto* the old proprietary system of medical education. But it turned out good doctors and it could not have been all bad. In fact, the course system of teaching on which the proprietary school was organized has in it a greater possibility for development for the capable student than is possessed by any hard and fast arrangement of courses of instruction with fixed hours of attendance and of duration and fixed content of subject. American medical schools were founded on the best traditions of the 18th century as learned at the schools of England and Edinburgh under Hunter, Munro and Cullen. They were developed in the 19th century by adding to the work in hospital and deadhouse of Bright, Hodgkin, Walsh, Stokes and Addison, the best methods of the French schools brought home from the Clinics of Laennec, Bichat, Andral, Corvissart and Louis. American medicine produced results under the leadership in internal medicine of such men as Alonzo Clark, DaCosta, Delafield, Fitz, Janeway, Leidy, Loomis, Minot, Osler, Pepper, Shattuck, Stille, in spite of the handicaps of the proprietary system under which they labored. In 1900, the younger generation of American graduates had come under the influence of the German Universities and the reforms of the past 25 years show the result. The influence of Pasteur in France, and Lister

in England were supplemented by a new influence.

The German University grew into a power in medical education when, about 1870, it became a purely scientific force and lost, for the time, its political taint. The German system under Skoda, Billroth, Virchow, Bamberger, Neusser, Nothnagle, Leyden, Gerhardt and others developed several new ideas of organization and procedure. First, that advancement in university rank should depend on achievement in scientific work and research, also that each university chair and control of hospital service or clinical institute should be combined on a single appointee and finally that the central authority of the state should recognize any course in any recognized university as of equal value so far as it constituted a part of the education of the individual student and was offered by him for credit in the State examination for licensure. Such a system gave an elasticity to medical education, a power of choice to the students enabling them to wander from university to university in periods of semester attendance, which have never been known to the American system of university organization. Such a plan puts each university at the mercy of the critical and stern judgment of the young, earnest and thoughtful students of the whole country. If such a system had been applied under State supervision to the proprietary medical schools of America, it is conceivable that a better result would have followed than is the case today. In any event and under any organization, the success or failure of American, or any other system of medical education, will depend not on the details enforced or self-imposed, but on the personality of the Billroths, the Oslers, the Virchows and the Pasteurs, on the leaders of the profession and on no other condition.

---

## VACCINATION AND SMALLPOX

By FREDERICK W SEARS, M.D.,

SYRACUSE N. Y.

**M**Y purpose in presenting this paper tonight is to call attention to certain facts regarding the increased prevalence of smallpox throughout the United States and to some of the causes responsible for its spread, and to urge the more general adoption of the improved methods in vaccination.

There has been a considerable increase in the incidence of smallpox throughout the United States during the last ten years which is undoubtedly due to a general relaxation in the

enforcement of present laws on vaccination and in many states the repeal of compulsory vaccination laws. This relaxation is probably due to the mild character of the disease which has prevailed up to within the last two or three years.

In 1923 the United States ranked third among the civilized nations in the number of smallpox cases reported, being only exceeded by India and Russia. From incomplete reports received for 1924, the indications are that the United States will rank second. This is quite a shock to our pride

course of a disease. The teaching of older clinicians has been forgotten in the worship of faithless idols and the present day is searching for new specifics to cure and for easy short cuts to diagnosis. It was Christian Fenger, of Chicago, who said that the microscope is only a symptom, and Edward G. Janeway, of New York, that the only value of the Widal reaction was to give him when it was absent a certain number more of consultations for diagnosis. The physician of today has forgotten that typhoid and the pox were well-known and diagnostic long before Widal and Wassermann were born, and before the causative germs of these diseases were discovered by Eberth and Schaudinn. The teachers of these recent graduates in medicine seem to me to miss the special needs of their followers. They are forever hunting the snark and lecturing on the ichthyosaurus while their pupils are unable to recognize the cimex lectuarius, or a common cold.

It is impossible to close this discussion without some reference to the recently published article by Dr. Wm. A. Pusey on "Medical Education and Medical Service." An attack on the expensiveness of medical education by the President of the American Medical Association is likely to be misinterpreted as an attack on education itself and reactionary influences may try to lean on this article to bring about a reduction in the instruction in every branch of medicine. Whether President Pusey has hit on the remedy for the faulty distribution of physicians in rural communities or not is not a point to be discussed in this report. It is important that President Pusey has called attention to the question that the expense of time and money in getting a modern medical education is the cause of the exclusion of poorer boys of the best minds from the profession of medicine. It is not so much the large cost in money that is important but the excessive cost in time that demands serious consideration and correction. Nor is it a question of medical education alone. The whole system of education is at fault. The child is taught to make of his education a play or game. The boy is filled full of facts to be forgotten, and is not given a real knowledge of how to study or a habit of concentration of effort. The youth at college is given too much choice and selection in his education. He is not compelled to carry everything begun to a conclusion. The course in high school and college should be so graded and taught that the average age of a bachelor of arts should not exceed 21 years. During all this time from 13 up to 21 years of age, the student should live a routine of work and play in a proportion of one to one and a half as to time consumed. At the age of 21 he should be ready to go to work in earnest, he

should have his bachelor's degree, and if he will be a medical student he should have an opportunity to fulfil the requirements of 4000 curriculum hours with 4000 hours of extra curriculum reading within three years of 264 working days each instead of spreading the same work as now required by law over four years of 156 days each. His ratio of work to play is still kept in the medical curriculum of today at the college ratio of one to one and a half. The medical student is a man, he can be no weakling. His ratio of work to play should be that of other men or about two and a half of work to one of play. This would mean eight weeks of vacation and 44 weeks of six days each of work, and each day would be of ten working hours duration. Dr. Pusey's claim for a reduction of expenditure should apply to the reduction of vacation time and not to a reduction in the required amount of instruction or of study. To accomplish this end, state control of medical education must give up its present double method of measurement both by length of each subject course and by total length of the whole course, as well. The state will still remain the final judge of the results and by examination can determine who is fit and who unfit to be admitted to the license to practice within its borders. Educators and legislators both must appreciate that medical education is a life's work for men and women over 21 years of age and not a job for boys and girls. It is not to be measured in periods of calendar time, but by the yardstick of hours of accomplishment.

Such a change in the medical curriculum was formulated as a possible war measure and presented on this platform in 1918 by Commissioner Downing, of New York. Some of the New York Schools at that time held continuous sessions for their 3rd and 4th year students and graduated the classes of 1918 and 1919 in February instead of in June. The regular organization of the University of Chicago for continuous sessions dividing the calendar year into four terms of three months each, is a demonstration of what can be done in this direction. But the law, with its restrictions of time and its enforced vacations for medical students, has always prevented the students of Rush Medical College from securing the full benefit of the curriculum of their own institution and thereby saving material time during their education. It will not be easy to undo the fixed habits of administration and of the legal processes of a quarter century. It is easier to make laws than it is to unmake or even to reform them, especially when the law demands some form of restriction. This country was founded on the decalogue of Moses, it adopted a constitution of checks and re-

straints, it went through the world war on the "thou shalt nots" of its President. This country is ruled by and loves its prohibitions, whether it be the prohibition of cigarettes or the prohibition of medical education, which denies to any student, however capable or diligent, the privilege of learning his profession any faster than is possible for the laziest and dullest student who can scrape through in four years, the minimum requirements of the university and licensing board of his State.

It is customary to condemn *in toto* the old proprietary system of medical education. But it turned out good doctors and it could not have been all bad. In fact, the course system of teaching on which the proprietary school was organized has in it a greater possibility for development for the capable student than is possessed by any hard and fast arrangement of courses of instruction with fixed hours of attendance and of duration and fixed content of subject. American medical schools were founded on the best traditions of the 18th century as learned at the schools of England and Edinburgh under Hunter, Munro and Cullen. They were developed in the 19th century by adding to the work in hospital and deadhouse of Bright, Hodgkin, Walsh, Stokes and Addison, the best methods of the French schools brought home from the Clinics of Laennec, Bichat, Andral, Corvissart and Louis. American medicine produced results under the leadership in internal medicine of such men as Alonzo Clark, DaCosta, Delafield, Fitz, Janeway, Leidy, Loomis, Minot, Osler, Pepper, Shattuck, Stille, in spite of the handicaps of the proprietary system under which they labored. In 1900, the younger generation of American graduates had come under the influence of the German Universities and the reforms of the past 25 years show the result. The influence of Pasteur in France, and Lister

in England were supplemented by a new influence.

The German University grew into a power in medical education when, about 1870, it became a purely scientific force and lost, for the time, its political taint. The German system under Skoda, Billroth, Virchow, Bamberger, Neusser, Nothnagle, Leyden, Gerhardt and others, developed several new ideas of organization and procedure. First, that advancement in university rank should depend on achievement in scientific work and research, also that each university chair and control of hospital service or clinical institute should be combined on a single appointee and finally that the central authority or the state should recognize any course in any recognized university as of equal value so far as it constituted a part of the education of the individual student and was offered by him for credit in the State examination for licensure. Such a system gave an elasticity to medical education, a power of choice to the students enabling them to wander from university to university in periods of semester attendance, which have never been known to the American system of university organization. Such a plan puts each university at the mercy of the critical and stern judgment of the young, earnest and thoughtful students of the whole country. If such a system had been applied under State supervision to the proprietary medical schools of America, it is conceivable that a better result would have followed than is the case today. In any event and under any organization, the success or failure of American, or any other system of medical education, will depend not on the details enforced or self-imposed, but on the personality of the Billroths, the Oslers, the Virchows and the Pasteurs, on the leaders of the profession and on no other condition.

## VACCINATION AND SMALLPOX

By FREDERICK W. SEARS, M.D.,

SYRACUSE, N. Y.

**M**Y purpose in presenting this paper tonight is to call attention to certain facts regarding the increased prevalence of smallpox throughout the United States and to some of the causes responsible for its spread, and to urge the more general adoption of the improved methods in vaccination.

There has been a considerable increase in the incidence of smallpox throughout the United States during the last ten years which is undoubtedly due to a general relaxation in the

enforcement of present laws on vaccination and in many states the repeal of compulsory vaccination laws. This relaxation is probably due to the mild character of the disease which has prevailed up to within the last two or three years.

In 1923 the United States ranked third among the civilized nations in the number of smallpox cases reported, being only exceeded by India and Russia. From incomplete reports received for 1924, the indications are that the United States will rank second. This is quite a shock to our pride.

course of a disease. The teaching of older clinicians has been forgotten in the worship of faithless idols and the present day is searching for new specifics to cure and for easy short cuts to diagnosis. It was Christian Fenger, of Chicago, who said that the microscope is only a symptom, and Edward G. Janeway, of New York, that the only value of the Widal reaction was to give him when it was absent a certain number more of consultations for diagnosis. The physician of today has forgotten that typhoid and the pox were well-known and diagnostic long before Widal and Wassermann were born, and before the causative germs of these diseases were discovered by Eberth and Schaudinn. The teachers of these recent graduates in medicine seem to me to miss the special needs of their followers. They are forever hunting the snark and lecturing on the ichthyosaurus while their pupils are unable to recognize the *cimex lectuarius*, or a common cold.

It is impossible to close this discussion without some reference to the recently published article by Dr. Wm. A. Pusey on "Medical Education and Medical Service." An attack on the expensiveness of medical education by the President of the American Medical Association is likely to be misinterpreted as an attack on education itself and reactionary influences may try to lean on this article to bring about a reduction in the instruction in every branch of medicine. Whether President Pusey has hit on the remedy for the faulty distribution of physicians in rural communities or not is not a point to be discussed in this report. It is important that President Pusey has called attention to the question that the expense of time and money in getting a modern medical education is the cause of the exclusion of poorer boys of the best minds from the profession of medicine. It is not so much the large cost in money that is important but the excessive cost in time that demands serious consideration and correction. Nor is it a question of medical education alone. The whole system of education is at fault. The child is taught to make of his education a play or game. The boy is filled full of facts to be forgotten, and is not given a real knowledge of how to study or a habit of concentration of effort. The youth at college is given too much choice and selection in his education. He is not compelled to carry everything begun to a conclusion. The course in high school and college should be so graded and taught that the average age of a bachelor of arts should not exceed 21 years. During all this time from 13 up to 21 years of age, the student should live a routine of work and play in a proportion of one to one and a half as to time consumed. At the age of 21 he should be ready to go to work in earnest, he

should have his bachelor's degree, and if he will be a medical student he should have an opportunity to fulfil the requirements of 4000 curriculum hours with 4000 hours of extra curriculum reading within three years of 264 working days each instead of spreading the same work as now required by law over four years of 156 days each. His ratio of work to play is still kept in the medical curriculum of today at the college ratio of one to one and a half. The medical student is a man, he can be no weakling. His ratio of work to play should be that of other men or about two and a half of work to one of play. This would mean eight weeks of vacation and 44 weeks of six days each of work, and each day would be of ten working hours duration. Dr. Pusey's claim for a reduction of expenditure should apply to the reduction of vacation time and not to a reduction in the required amount of instruction or of study. To accomplish this end, state control of medical education must give up its present double method of measurement both by length of each subject course and by total length of the whole course, as well. The state will still remain the final judge of the results and by examination can determine who is fit and who unfit to be admitted to the license to practice within its borders. Educators and legislators both must appreciate that medical education is a life's work for men and women over 21 years of age and not a job for boys and girls. It is not to be measured in periods of calendar time, but by the yardstick of hours of accomplishment.

Such a change in the medical curriculum was formulated as a possible war measure and presented on this platform in 1918 by Commissioner Downing, of New York. ## VACCINATION AND SMALLPOX

By FREDERICK W SEARS, M.D.,

SYRACUSE, N. Y.

**M**Y purpose in presenting this paper tonight is to call attention to certain facts regarding the increased prevalence of smallpox throughout the United States and to some of the causes responsible for its spread, and to urge the more general adoption of the improved methods in vaccination.

There has been a considerable increase in the incidence of smallpox throughout the United States during the last ten years which is undoubtedly due to a general relaxation in the

enforcement of present laws on vaccination and in many states the repeal of compulsory vaccination laws. This relaxation is probably due to the mild character of the disease which has prevailed up to within the last two or three years.

In 1923 the United States ranked third among the civilized nations in the number of smallpox cases reported, being only exceeded by India and Russia. From incomplete reports received for 1924, the indications are that the United States will rank second. This is quite a shock to our pride

as medical men and public health workers, and a reflection upon the intelligence of our legislators. In this respect I wish to exempt the City of Syracuse from any such reflection. Were all communities as diligent in enforcement of the vaccination laws and as careful in the methods of vaccination as Syracuse has been for the last quarter of a century, there would be little cause for anxiety. Our chief concern in the prevention of smallpox is among adults who have adopted Syracuse as their home, coming from sections of the country where compulsory vaccination has not been carried out in their schools. It is among these people that all of our initial cases occur, however, during the fifteen years in which I have been more or less closely associated with the health work of Syracuse these outbreaks have been confined to the homes of the initial case which is undoubtedly due to the compulsory vaccination which is so thoroughly carried on by our local health department. The serious epidemic which this City went through in 1875 and 1876 was a lesson in vaccination which Syracuse has never forgotten.

Incomplete reports for the United States for the year 1924 gives the total number of cases of smallpox reported that year as 49,819. From January 1st to July 1st, 1924, there were reported in the States of Michigan 3,999 cases of smallpox. From January 1st to November 1st, 1924, Detroit alone reported 1,592 cases with 164 deaths. From January 1st to August 1st, 1924, Minnesota reported 1,613 cases, 193 of which were of the malignant type with 40 deaths, compulsory vaccination was given up in that State in 1903. The case mortality rate for smallpox in Arizona in 1922 was 28.6 per cent, in Colorado for the same year it was 24.9 per cent.

At the beginning of the outbreak in Detroit last year 26 per cent of its population was unvaccinated and 44 per cent was in need of revaccination. During 1924 New York State had the largest number of cases of smallpox recorded for many years (488 cases, 451 of them had never been vaccinated), some were of the malignant type.

A severe type of smallpox may convey a mild attack to a person vaccinated a number of years previously who in turn may transmit the severe type. It is plainly evident that unless laws are more stringently enforced and new laws enacted where needed, the situation will soon become a most serious one, and it is our duty as physicians to urge our legislators to do their duty along these lines.

The question as to the value of vaccination and the possibility of eradicating smallpox by this means was settled by Jenner once for all time a century and a quarter ago. However, careless methods in vaccination and ignorance

or neglect in its after-care has been the chief weapon in the hands of anti-vaccinationists in securing adverse legislation. Greater refinement in the manufacture of vaccine virus which has been under government supervision since 1902 and the more careful and sane methods employed in vaccination has rendered this a perfectly safe and harmless procedure.

There are three recognized methods for efficient and safe vaccination. In all of these methods we should confine the vaccination area with in a surface not to exceed one-eighth of an inch in diameter. The proper site for vaccination is the one which Jenner himself selected, that is, at the insertion of the deltoid muscle on the left arm. With all methods the arm should be cleansed with soap and water or by some volatile antiseptic liquid and allowed to dry. A small drop of the virus is placed on the site for vaccination. The three methods are, first, a one-eighth of an inch linear incision through the virus not sufficiently deep to cause bleeding. Second, three or four superficial punctures with a sharp needle through the virus. Third, the so-called drill method of the same depth. In all methods the surface should be allowed to dry in the air and no dressings applied until a take is assured when either a very thin covering of sterile gauze is placed over the wound or what is equally efficient the pinning of sterile gauze on the lining of the sleeve which covers the vaccination wound. In no case should we use a shield or a tight bandage. These methods used with potent vaccine should give one hundred per cent takes in all primary cases and no disfiguring scar. The physician who consents to vaccinate on the leg is courting trouble unless the patient consents to remain in bed during the active course of the vaccination. Vaccine virus should be stored at as near the freezing temperature as possible, as freezing does not injure it. It rapidly loses its potency when kept at room temperatures. When we consider that successful vaccination performed within three days after exposure to smallpox will prevent the disease and from the fourth to the seventh day of exposure successful vaccination will modify the course of the disease in unprotected persons, and that after the eighth day following exposure it has no effect upon the disease the importance of using potent vaccine in checking an outbreak of smallpox becomes very evident.

What are the contra-indications to vaccination? In the presence of an epidemic I know of none. In the recent Detroit epidemic 3,346 hospital patients were vaccinated. Of these patients 90 were cases of erysipelas, 773 were obstetric cases, 876 were new born babies, 21 were venereal cases, also numerous cases of diphtheria, scarlet fever, measles and tuberculosis and no untoward results occurred. In normal times it

is unwise to vaccinate in the presence of an open infection for fear of infecting the wound. Among careless people who have the care of horses it is advisable to give a prophylactic dose of tetanus antitoxin at the time of vaccination. Owing to an outbreak of a serious form of the disease in Rochester last summer 103,000 people were vaccinated within the last few months with no serious results. Rochester uses the drill method.

During the recent epidemic in Detroit 817,000 vaccinations were performed, 500,000 of which were done during May and the early part of June. Dr. Vaughan writes that there were a few sore arms but not one of which in any way could be called serious. The epidemic ended the last of June. The vaccine was delivered fresh every two hours. At one period of the work 75,000 points were delivered daily. The method used in Detroit was two linear incisions. No case of smallpox occurred in Detroit among exposed people who had a vaccination scar which was five years old or less. There were twelve cases among exposed persons who had vaccination scars from six years to ten years old, thirty-five with scars from eleven to twenty-five years standing and sixty-six with scars over twenty-five years old. Only seven per cent of the cases and no deaths among the people who had a typical vaccination scar.

Dr. John Simon, the famous London Health official, brought out the fact many years ago that vaccination gives a greater protection against smallpox than does having the disease itself.

Should a case of smallpox occur following a successful vaccination the disease is nearly always of the mild type. Among the secondary cases of smallpox occurring in individuals who have had the disease earlier in life a large percentage are fatal. This was borne out in a recent outbreak in Minnesota, in which outbreak there were two fatal cases of smallpox in persons who had had the disease in childhood and no deaths occurring among those who had ever been successfully vaccinated.

Failure to get a take on repeated vaccination does not indicate that the person will not take smallpox, neither does a secondary successfully vaccination indicate that the individual would have taken smallpox had he been exposed to it.

In people who have been successfully vaccinated an immunity reaction can usually be seen at the site of revaccination in the form of a small red pimple which develops within twenty-four hours after vaccination and fades out in about forty-eight hours. This reaction is useful in the presence of outbreaks in determining the period of isolation.

A large percentage of the outbreaks which occur are due to errors in diagnosis of the initial

case. This was true of the recent outbreak in Johnson City and in many other outbreaks in New York State. The outbreak of the more serious cases in Detroit was thought to be due to a hemorrhagic case which occurred in Windsor and which was not diagnosed. In the absence of an epidemic hemorrhagic cases are rarely diagnosed.

In my opinion one of the chief causes of failure in making a diagnosis of smallpox is in giving too much attention to the appearance of the eruption and not sufficient to the history of the case. There is little difficulty in making a diagnosis of smallpox if a suitable history of the case can be obtained. In the order of their importance I should place first, the history of four days of more or less severe constitutional symptoms, including an initial chill, nausea, fever, severe headache and backache and frequently delirium, the temperature ranging from 102 or 105 or more, second, the almost complete cessation of the constitutional symptoms on the appearance of the eruption, the temperature going to 98 degrees, and in the majority of cases if properly cared for, not again going above the normal point, third, the eruption begins on the forehead and extends rapidly downward over the surface of the body, selecting chiefly the exposed surfaces, as the face, forearms, wrists, legs, palms of the hands and the soles of the feet. The eruption reaches its height of development about the end of a week, and is always of the same stage of development on that portion of the body on which it may appear. In chickenpox, the disease most commonly confused with smallpox, the eruption is preceded by only one day of illness, the temperature gradually rising with the development of the successive crops of the eruption, which is most profuse on the chest and other covered portions of the body. I have never seen a case of chickenpox without a rise of temperature in its early eruptive stage, and I have never seen a case of smallpox with a rise of temperature during the early stage of the eruption. The eruption of chickenpox always shows the mixed variety of lesions in any particular location and tends to dry down and form crusts at the end of four or five days.

To those who are unacquainted with smallpox the tendency is to consider the case as one of smallpox if the eruption is profuse and the patient seems very ill, notwithstanding the fact that a case of smallpox may exist with fewer lesions than would ever occur in any case of adult chickenpox.

I wish to show a few slides to illustrate some of the points spoken of in the paper.

## OBSERVATIONS ON CHRONIC OTORRHEA IN THE INSANE

By JAY DASHIEL WHITHAM, M.D.,

NEW YORK CITY

MUCH has been written in recent years regarding the role focal infections play in the production of certain forms of mental diseases. There is no doubt that severe infectious processes always produce temporary derangements of the sensorium. When such processes are long continued or exhausting, in many cases the result is a prolonged or permanent psychiatric condition. It seems possible that extensive necrosis in the temporal bone with continuous absorption of virulent toxic products in a mentally unstable individual is an important factor in aggravating a psychosis. With this idea in mind the writer has operated on seven mental cases, with the object in each of curing a chronic discharging ear.

These were selected from scores of mental cases who had chronic ears, for, generally speaking, only those were operated on who had a very foul discharge with granulations indicating the presence of an extensive necrosis in the temporal bone. After examining the ears of many hundred insane the writer has been astonished at the relative frequency of chronic suppuration.

The writer wishes to take this opportunity to thank Dr. William C. Garvin, former Superintendent of Kings Park State Hospital for the Insane, for his co-operation in this work and to give credit to Dr. Milton M. Grover for the skillful post-operative care the following cases received.

Case 1. Frank W., age 24. On admission to the hospital, July 22, 1922, this man showed a well-marked hebephrenic type of dementia praecox. He was voluble, confused and rambling in speech. His memory and orientation were intact. His mental age was eleven years. He had constant auditory hallucinations. Physical examination was practically negative except for a foul discharge from the right ear. The ear showed an almost complete destruction of the drum and a large quantity of granulation tissue. He had had this condition as long as he could remember.

On August 27, 1922, a radical mastoid operation was performed on this ear.

On September 18, 1922, the ear was almost healed, but no mental improvement was apparent.

October 20, 1923. The right ear has remained clean and dry. He has shown a marked mental improvement. He is pleasant and agreeable in manner and is no longer troubled with hearing voices. He co-operates readily and is clean and neat in appearance.

On that date he was sent home from the hospital on parole.

Case 2. Florence M., age 35. This woman was admitted to the hospital on March 4, 1922, with the diagnosis of psychopathic personality with excited episodes. She was restless, childish, voluble and dangerous at times. Her age level was nine years. She apparently had no insight into her mental condition. From a relative it was learned that the discharge she had from her left ear had been present since early childhood. This discharge was fairly profuse, and on removing it, a large posterior marginal perforation was seen.

On October 8, 1922, a radical mastoid operation was performed.

December 16, 1922, the cavity was healed and dry. The patient was neat, clean and alert. Mentally she was so far improved that she was sent home.

Case 3. James L. This man was suffering from paresis. He had a copious foul discharge from his left ear about which he complained a great deal.

On December 31, 1921, a radical mastoid operation was performed. Following this the patient had a permanent facial paralysis, although the writer was not conscious of exposing or touching the nerve during the operation. His ear healed perfectly, but his mental condition grew steadily worse until his death eight months later from general paresis.

Case 4. George T. This patient had dementia praecox, associated with a foul, scanty discharge from his left ear. It was ascertained that he had had this discharge for at least four years. Examination of the ear showed a posterior marginal perforation involving Shrapnell's membrane. A probe passed through this perforation toward the antrum. It seemed to touch exposed rough bone.

On June 25, 1922, a radical mastoid operation was performed.

This resulted in a dry ear after many weeks of treatment, including a re-administration of ether and removal of granulations through the meatus. This patient was paroled to his home greatly improved mentally several months later.

Case 5. R. H., male, age 43. This patient had dementia praecox, paranoid type. At the time of operation he had numerous ideas of persecution, auditory hallucinations, and obsessions. His speech was rambling and incoherent. The duration of these symptoms was doubtful. He had a continuous scanty dis-

charge from his left ear with a marginal perforation

On November 11, 1923, a radical mastoid operation was performed. The entire mastoid was ivory-like without cell structure. The antrum was apparently entirely obliterated. The operation was completed by using the horizontal canal as a landmark.

On January 21, 1924, the ear was healed. His memory, orientation and grasp of current topics was defective. Since then he has been working in the hospital dining hall and is in good general physical condition. He no longer reacts to hypochondriacal trends as before, but complains at times of pain in his left ear.

Case 6 M. H., female, age 32. Former occupation, dictaphone operator.

Diagnosis Dementia praecox, paranoid type. In July, 1923, she lost her way returning home from work and for several days after this she had a headache, which felt like a tight band pressing on her forehead. At first she slept a great deal, but after a few days she grew restless and felt that some great harm was coming to her. According to relatives she then became unmanageable, refused food, alleging it was poisoned.

On admission it was noted that she was obstructive and showed emotional instability. It was noted that she had a moderately large thyroid gland and a fine tremor of her fingers. She weighed 187 pounds. The left ear showed a scanty foul discharge. The canal was narrow and the perforation was covered with granulations. She had an O. M. P. C. residual in the right ear with good hearing. The discharge from the left ear had been present since childhood.

On October 28, 1923, a left radical mastoid operation was performed and extensive necrosis was found about the antrum and adjacent bone.

February 18, 1924. The ear was dry and healed. Her appearance was quite natural. Although her insight into her previous condition was not complete she was wonderfully improved and was sent home on parole.

Case 7 Mary T., age 26. Diagnosis Dementia praecox, hebephrenic type. This patient was simple, childish, destructive, and very dull. Her physical condition was very poor. Haemoglobin 60%. Albumin was present in the urine.

On August 6, 1921, she complained of pain

in right lower jaw. A swelling was noted below the angle of the jaw. Her temperature was 104. The next day the swelling had greatly increased in size and involved the neck and parotid region. Great quantities of pus then began to flow continually through the right auditory meatus. Culture showed staphylococci streptococci and Gram positive encapsulated diplococci. A paralysis of the right facial nerve was then noted for the first time.

On August 9th an effort was made to examine the ear, but the drum could not be seen owing to the continual discharge from the abscess in the neck, which had grown very large.

It was thought the pus was flowing from a perforation in the floor of the cartilaginous canal. Under light anaesthesia two large incisions were made in the neck, a great quantity of thick white pus was evacuated and through and through drainage was established. Within a month the neck had healed, but the aural discharge and the facial paralysis had persisted.

On October 17, 1921, a right radical mastoid operation was performed. At this operation a large sequester was found which included the entire posterior canal wall and part of the mastoid tip.

On February 10, 1922, the ear was dry and healed, the facial paralysis, however, persisted. Evidence of pulmonary tuberculosis was present in both lungs.

On July 14, 1922, death occurred from pulmonary tuberculosis. No autopsy was permitted. It seems probable that the ear condition was tuberculous, although no tubercle bacilli could be found in the smears.

To summarize, four of the seven cases showed marked mental improvement, two showed considerable improvement, and in two patients the operation did nothing to arrest the progress of the disease. In all cases the operation cured the aural suppuration.

One of the failures was a case of general paresis, which should not have been operated upon, and would not have been touched had the diagnosis been certain at the time of the operation, the other failure died of pulmonary tuberculosis ten months later. There is no intention to claim directly or by inference that any patients were cured of insanity, but the mental improvement after operation was so striking in some of our patients that we feel amply rewarded for our efforts.

## OBSERVATIONS ON CHRONIC OTORRHEA IN THE INSANE

By JAY DASHIEL WHITHAM, M.D.,  
NEW YORK CITY

MUCH has been written in recent years regarding the role focal infections play in the production of certain forms of mental diseases. There is no doubt that severe infectious processes always produce temporary derangements of the sensorium. When such processes are long continued or exhausting, in many cases the result is a prolonged or permanent psychiatric condition. It seems possible that extensive necrosis in the temporal bone with continuous absorption of virulent toxic products in a mentally unstable individual is an important factor in aggravating a psychosis. With this idea in mind the writer has operated on seven mental cases, with the object in each of curing a chronic discharging ear.

These were selected from scores of mental cases who had chronic ears, for, generally speaking, only those were operated on who had a very foul discharge with granulations indicating the presence of an extensive necrosis in the temporal bone. After examining the ears of many hundred insane the writer has been astonished at the relative frequency of chronic suppuration.

The writer wishes to take this opportunity to thank Dr. William C. Garvin, former Superintendent of Kings Park State Hospital for the Insane, for his co-operation in this work and to give credit to Dr. Milton M. Grover for the skillful post-operative care the following cases received.

Case 1 Frank W., age 24. On admission to the hospital, July 22, 1922, this man showed a well-marked hebephrenic type of dementia praecox. He was voluble, confused and rambling in speech. His memory and orientation were intact. His mental age was eleven years. He had constant auditory hallucinations. Physical examination was practically negative except for a foul discharge from the right ear. The ear showed an almost complete destruction of the drum and a large quantity of granulation tissue. He had had this condition as long as he could remember.

On August 27, 1922, a radical mastoid operation was performed on this ear.

On September 18, 1922, the ear was almost healed, but no mental improvement was apparent.

October 20, 1923. The right ear has remained clean and dry. He has shown a marked mental improvement. He is pleasant and agreeable in manner and is no longer troubled with hearing voices. He co-operates readily and is clean and neat in appearance.

On that date he was sent home from the hospital on parole.

Case 2 Florence M., age 35. This woman was admitted to the hospital on March 4, 1922, with the diagnosis of psychopathic personality with excited episodes. She was restless, childish, voluble and dangerous at times. Her age level was nine years. She apparently had no insight into her mental condition. From a relative it was learned that the discharge she had from her left ear had been present since early childhood. This discharge was fairly profuse, and on removing it, a large posterior marginal perforation was seen.

On October 8, 1922, a radical mastoid operation was performed.

December 16, 1922, the cavity was healed and dry. The patient was neat, clean and alert. Mentally she was so far improved that she was sent home.

Case 3 James L. This man was suffering from paresis. He had a copious foul discharge from his left ear about which he complained a great deal.

On December 31, 1921, a radical mastoid operation was performed. Following this the patient had a permanent facial paralysis, although the writer was not conscious of exposing or touching the nerve during the operation. His ear healed perfectly, but his mental condition grew steadily worse until his death eight months later from general paresis.

Case 4 George T. This patient had dementia praecox, associated with a foul, scanty discharge from his left ear. It was ascertained that he had had this discharge for at least four years. Examination of the ear showed a posterior marginal perforation involving Shrapnell's membrane. A probe passed through this perforation toward the antrum. It seemed to touch exposed rough bone.

On June 25, 1922, a radical mastoid operation was performed.

This resulted in a dry ear after many weeks of treatment, including a re-administration of ether and removal of granulations through the meatus. This patient was paroled to his home greatly improved mentally several months later.

Case 5 R. H., male, age 43. This patient had dementia praecox, paranoid type. At the time of operation he had numerous ideas of persecution, auditory hallucinations, and obsessions. His speech was rambling and incoherent. The duration of these symptoms was doubtful. He had a continuous scanty dis-

charge from his left ear with a marginal perforation

On November 11, 1923, a radical mastoid operation was performed. The entire mastoid was ivory-like without cell structure. The antrum was apparently entirely obliterated. The operation was completed by using the horizontal canal as a landmark.

On January 21, 1924, the ear was healed. His memory, orientation and grasp of current topics was defective. Since then he has been working in the hospital dining hall and is in good general physical condition. He no longer reacts to hypochondriacal trends as before, but complains at times of pain in his left ear.

Case 6 M H, female, age 32. Former occupation, dictaphone operator.

Diagnosis Dementia praecox, paranoid type. In July, 1923, she lost her way returning home from work and for several days after this she had a headache, which felt like a tight band pressing on her forehead. At first she slept a great deal, but after a few days she grew restless and felt that some great harm was coming to her. According to relatives she then became unmanageable, refused food, alleging it was poisoned.

On admission it was noted that she was obstructive and showed emotional instability. It was noted that she had a moderately large thyroid gland and a fine tremor of her fingers. She weighed 187 pounds. The left ear showed a scanty foul discharge. The canal was narrow and the perforation was covered with granulations. She had an O M P C residual in the right ear with good hearing. The discharge from the left ear had been present since childhood.

On October 28, 1923, a left radical mastoid operation was performed and extensive necrosis was found about the antrum and adjacent bone.

February 18, 1924. The ear was dry and healed. Her appearance was quite natural. Although her insight into her previous condition was not complete she was wonderfully improved and was sent home on parole.

Case 7 Mary T, age 26. Diagnosis Dementia praecox, hebephrenic type. This patient was simple, childish, destructive, and very dull. Her physical condition was very poor. Haemoglobin 60%. Albumin was present in the urine.

On August 6, 1921, she complained of pain

in right lower jaw. A swelling was noted below the angle of the jaw. Her temperature was 104. The next day the swelling had greatly increased in size and involved the neck and parotid region. Great quantities of pus then began to flow continually through the right auditory meatus. Culture showed staphylococci streptococci and Gram positive encapsulated diplococci. A paralysis of the right facial nerve was then noted for the first time.

On August 9th an effort was made to examine the ear, but the drum could not be seen owing to the continual discharge from the abscess in the neck, which had grown very large.

It was thought the pus was flowing from a perforation in the floor of the cartilaginous canal. Under light anaesthesia two large incisions were made in the neck, a great quantity of thick white pus was evacuated and through and through drainage was established. Within a month the neck had healed, but the aural discharge and the facial paralysis had persisted.

On October 17, 1921, a right radical mastoid operation was performed. At this operation a large sequester was found which included the entire posterior canal wall and part of the mastoid tip.

On February 10, 1922, the ear was dry and healed, the facial paralysis, however, persisted. Evidence of pulmonary tuberculosis was present in both lungs.

On July 14, 1922, death occurred from pulmonary tuberculosis. No autopsy was permitted. It seems probable that the ear condition was tuberculous, although no tubercle bacilli could be found in the smears.

To summarize, four of the seven cases showed marked mental improvement, two showed considerable improvement, and in two patients the operation did nothing to arrest the progress of the disease. In all cases the operation cured the aural suppuration.

One of the failures was a case of general paresis, which should not have been operated upon, and would not have been touched had the diagnosis been certain at the time of the operation, the other failure died of pulmonary tuberculosis ten months later. There is no intention to claim directly or by inference that any patients were cured of insanity, but the mental improvement after operation was so striking in some of our patients that we feel amply rewarded for our efforts.

## OBSERVATIONS ON CHRONIC OTORRHEA IN THE INSANE

By JAY DASHIEL WHITHAM, M.D.,

## THE TREATMENT OF CONGENITAL DEFORMITIES

By RICHMOND STEPHENS, M.D.,

NEW YORK CITY

**I**N commencing I wish to state briefly that Orthopædic Surgery has probably changed more in the last twenty years than any other branch of Medicine. Formerly it was considered merely "strap and buckle" work and was limited to very few conditions and practiced by comparatively few men. Lately the scope of the work has broadened and the specialty has become better known to the profession at large and I believe now that the general public is beginning to know what it means, although unfortunately the title is extremely unsatisfactory. Many people are confused and think that it is something like osteopathy, chiropractic or some of the other cults.

A few years ago the field of orthopædic surgery was practically limited to tuberculosis of bones and joints, certain paralyses, a few congenital deformities and some of the postural conditions. The treatment was always by means of braces or plaster-of-Paris and the only operations were tenotomies for the correction of contractures and simple evacuation of abscesses. Now a great deal of our work is operative and we are doing more along the line of bone and joint surgery. Fractures and dislocations, particularly the difficult ones or those with poor late results, such as mal or non-union, ankylosed joints, etc., are among the problems which we are handling.

At the present time we are doing a great deal of prophylactic work as is the case in all branches of medicine. At this time I would like to add my word of approval to the campaigns that are being carried on for routine periodic examinations. In this way many orthopædic conditions could be prevented or at least discovered early and treated before they become serious. Such conditions as weak foot, spinal curvature, mild paralyses, early tuberculosis and many others might be checked and the usual prolonged treatment and often deforming results might be eliminated.

In considering congenital deformities it is of the utmost importance that all infants should be thoroughly examined at birth as practically all of the conditions should have treatment instituted early.

There are several conditions of congenital origin which may not be discovered during infancy such as, anomalies of the vertebrae and cervical ribs which we will not discuss at this time. In passing I might also mention several conditions such as spina bifida deformities caused by amniotic bands, supernumerary bones or digits, syndactylism, etc. most of which require operative correction and many in which it is preferable to defer the treatment for some time. There is also a group of congenital deformities such as elevation of the Scapula (Sprengel's

shoulder), radioulna synostosis, Madelung's deformity, club hand, etc., which are infrequently seen and which require rather individual and highly specialized forms of treatment.

The more common congenital deformities which I do wish to cover are wry-neck or Torticollis, club foot or talipes and dislocation of the hip. These are seen relatively frequently and in the first two conditions there are many cases that can be relieved without the services of a specialist. It is impossible in a short time to go very deeply into the treatment but I will endeavor to outline it for all except the most resistant or extreme cases.

*Torticollis*—Although the congenital type is less common than the acquired, nevertheless we see it quite frequently. In making the diagnosis we must be certain that it is true muscular contraction and not secondary to some affection of the cervical spine or glands. It may be caused by an injury at birth and often one can see or feel an enlargement in the neck due to a hæmatoma or a muscle injury. In this type of case the treatment consists of light massage and frequent gentle manipulations to overcome the deformity. In the cases of real contracture the sterno-cleido-mastoid is always involved and with it there may be shortening of other structures. Sometimes the condition is not noticed until the child sits up or at least holds the head. The deformity is that which is produced by approximating the mastoid process to the sterno-clavicular joint. For example, in a right torticollis the head is tilted toward the right shoulder with the face to the left and the chin pointed up to the left. In infants we are able to cure most cases by simple stretching. The method is by holding the shoulder and stretching the sterno-mastoid to increase the distance between our two fixed points. The child will usually lie in its bed facing the left in a case of right torticollis. We find that because this seems to be the tendency the mother will place the bed so that the child can look out into the room which is the natural thing. Therefore, we may help the condition by having the bed so placed that in order to look out into the room the baby will have to turn the head in the opposite direction. In the average case this along with manipulations done to the count about twenty times, four or five times a day will give a complete cure. In obstinate or neglected cases we will find a resulting condition of asymmetry of the head and neck which will increase with age and which decreases the chances of an ultimate cure. We can only resort to operation by a subcutaneous tenotomy of the contracted muscle fibres or an open operation. Of course,

nobody desires a scar on his or her neck but the subcutaneous method is such blind surgery, much like the old methods of tonsillotomy that we should always avoid it except in the simplest cases. By the open method we do not run the risk of injury to the important structures in the neck and with a subcuticular stitch we can usually avoid an unsightly scar.

The after treatment consists of retaining the overcorrected position by means of plaster-of-Paris for a short time and then frequent manipulations to prevent a recurrence of the deformity. Formerly we used the plaster for several weeks but I now believe that the results are better by removing it in about two weeks and then starting manipulations and exercises. The after treatment should be continued for several months and the patient carefully observed to make certain that the deformity does not tend to recur.

*Lalipes*—Congenital club foot is easily recognized at birth and if treated early and efficiently can be cured in about ninety per cent of all cases in from a few weeks to a year. The proper time to start treatment is about the tenth day at which time the baby has usually regained birth weight, is feeding well and the skin is slightly tougher than at birth. Whatever the deformity may be, the aim is to stretch the foot into the directly opposed position. The most common type is equinovarus and we will make our remarks for such a case. In the mild cases simple stretching several times a day may be sufficient. In more severe cases it is necessary to stretch the foot and maintain it in the over-corrected position. Plaster-of-Paris is preferable to adhesive plaster as it maintains the position better and is not so liable to cause skin injury. One must be careful to avoid a tight plaster and at the same time to have one that can not be kicked off. The plaster should be reapplied every week. At each reapplication the foot is stretched and further correction should be obtained. This is continued until the foot remains in the over-corrected position. Then the plaster may be omitted and the foot held in an over-corrected attitude with adhesive strapping and then manipulations. As the child begins to walk we may have the shoes altered, by raising the outer border for equino-varus, etc. The patient must be watched for a long time. If there is any sign of recurrence, treatment should be reinstituted.

In older or relapsed cases the same method may be tried but these and the most serious cases may need operation such as wrenching, fasciotomy, tenotomy, capsulotomy, wedge, astraglectomy, etc. Untreated cases in older children or adults are difficult and results can not be expected to be so good.

*Congenital Dislocation of the Hip*—Congenital dislocation of the hip may be diagnosed at birth but usually is not found until the child begins to walk. Then the parents notice that there is a limp and an exaggerated lumbar lordosis. I can not say what the result would be in cases diagnosed before walking as we do not see them but it is my belief that they could be very easily reduced and in many cases would stay in place without any plaster or other support.

In the usual case we start treatment when the baby is trained sufficiently to dispense with diapers for in the use of plaster it is essential that they should not be wet. The chances of reduction are very good from this time up to about seven years. After seven we can rarely reduce a dislocated hip without an open operation. In all cases, however, we can usually determine the outcome, for if the head of the femur is not too high and if there is a good acetabulum we may expect to get a cure.

The common variety of dislocation is the one in which the head of the femur is above and behind the acetabulum and the treatment outlined here is for this type of case. Other forms of dislocation require special treatment. Let us consider a case of the most frequent sort. I will not go into the details of the operation but will describe the treatment briefly. The child must be anesthetized sufficient for complete relaxation. The hamstrings, adductors and flexors are stretched and the hip manipulated into place. A plaster spica is then applied to hold the hip in place, this usually being with the thigh rotated outward, abducted and hyper-extended into what is frequently called the "frog" position. The after treatment consists of maintaining the reduction with a change of plaster every six or eight weeks, each time bringing the thigh down a little toward the normal position. In the average case the treatment covers a period of about nine months.

If a hip can not be reduced in two or three attempts or if it can not be held in place after adequate reduction it is best to let it wait until the patient is a little older and then reduce it by an open operation. Such cases will usually show a shallow acetabulum or one filled with connective tissue or a so-called hour-glass constriction of the capsule.

I have endeavored to cover a lot of ground in a short time and have tried to outline the treatment of these congenital deformities in such a way that it would be of interest to all. I am of the opinion that we can all get a great deal more out of our County Medical Society meetings if we can take up subjects that will not be too special, and that can be discussed by all of the members.

## THE TREATMENT OF CONGENITAL DEFORMITIES

By RICHMOND STEPHENS, M.D.,

NEW YORK CITY

**I**N commencing I wish to state briefly that Orthopædic Surgery has probably changed more in the last twenty years than any other branch of Medicine. Formerly it was considered merely "strap and buckle" work and was limited to very few conditions and practiced by comparatively few men. Lately the scope of the work has broadened and the specialty has become better known to the profession at large and I believe now that the general public is beginning to know what it means, although unfortunately the title is extremely unsatisfactory. Many people are confused and think that it is something like osteopathy, chiropractic or some of the other cults.

A few years ago the field of orthopædic surgery was practically limited to tuberculosis of bones and joints, certain paralyses, a few congenital deformities and some of the postural conditions. The treatment was always by means of braces or plaster-of-Paris and the only operations were tenotomies for the correction of contractures and simple evacuation of abscesses. Now a great deal of our work is operative and we are doing more along the line of bone and joint surgery. Fractures and dislocations, particularly the difficult ones or those with poor late results, such as mal or non-union, ankylosed joints, etc., are among the problems which we are handling.

At the present time we are doing a great deal of prophylactic work as is the case in all branches of medicine. At this time I would like to add my word of approval to the campaigns that are being carried on for routine periodic examinations. In this way many orthopædic conditions could be prevented or at least discovered early and treated before they become serious. Such conditions as weak foot, spinal curvature, mild paralyses, early tuberculosis and many others might be checked and the usual prolonged treatment and often deforming results might be eliminated.

In considering congenital deformities it is of the utmost importance that all infants should be thoroughly examined at birth as practically all of the conditions should have treatment instituted early.

There are several conditions of congenital origin which may not be discovered during infancy such as, anomalies of the vertebrae and cervical ribs which we will not discuss at this time. In passing I might also mention several conditions such as spina bifida deformities caused by amniotic bands, supernumerary bones or digits syndactylism etc. most of which require operative correction and many in which it is preferable to defer the treatment for some time. There is also a group of congenital deformities such as elevation of the Scapula (Sprengel's

shoulder), radioulna synostosis, Madelung's deformity, club hand, etc., which are infrequently seen and which require rather individual and highly specialized forms of treatment.

The more common congenital deformities which I do wish to cover are wry-neck or Torticollis, club foot or talpes and dislocation of the hip. These are seen relatively frequently and in the first two conditions there are many cases that can be relieved without the services of a specialist. It is impossible in a short time to go very deeply into the treatment but I will endeavor to outline it for all except the most resistant or extreme cases.

*Torticollis*—Although the congenital type is less common than the acquired, nevertheless we see it quite frequently. In making the diagnosis we must be certain that it is true muscular contraction and not secondary to some affection of the cervical spine or glands. It may be caused by an injury at birth and often one can see or feel an enlargement in the neck due to a hematoma or a muscle injury. In this type of case the treatment consists of light massage and frequent gentle manipulations to overcome the deformity. In the cases of real contracture the sterno-cleido-mastoid is always involved and with it there may be shortening of other structures. Sometimes the condition is not noticed until the child sits up or at least holds the head. The deformity is that which is produced by approximating the mastoid process to the sterno-clavicular joint. For example, in a right torticollis the head is tilted toward the right shoulder with the face to the left and the chin pointed up to the left. In infants we are able to cure most cases by simple stretching. The method is by holding the shoulder and stretching the sterno-mastoid to increase the distance between our two fixed points. The child will usually lie in its bed facing the left in a case of right torticollis. We find that because this seems to be the tendency the mother will place the bed so that the child can look out into the room which is the natural thing. Therefore, we may help the condition by having the bed so placed that in order to look out into the room the baby will have to turn the head in the opposite direction. In the average case this along with manipulations done to the count about twenty times, four or five times a day will give a complete cure. In obstinate or neglected cases we will find a resulting condition of asymmetry of the head and neck which will increase with age and which decreases the chances of an ultimate cure. We can only resort to operation by a subcutaneous tenotomy of the contracted muscle fibres or an open operation. Of course,

nobody desires a scar on his or her neck but the subcutaneous method is such blind surgery, much like the old methods of tonsillotomy, that we should always avoid it except in the simplest cases. By the open method we do not run the risk of injury to the important structures in the neck and with a subcuticular stitch we can usually avoid an unsightly scar.

The after treatment consists of retaining the overcorrected position by means of plaster-of-Paris for a short time and then frequent manipulations to prevent a recurrence of the deformity. Formerly we used the plaster for several weeks but I now believe that the results are better by removing it in about two weeks and then starting manipulations and exercises. The after treatment should be continued for several months and the patient carefully observed to make certain that the deformity does not tend to recur.

*Talipes*—Congenital club foot is easily recognized at birth and if treated early and efficiently can be cured in about ninety per cent of all cases in from a few weeks to a year. The proper time to start treatment is about the tenth day at which time the baby has usually regained birth weight, is feeding well and the skin is slightly tougher than at birth. Whatever the deformity may be, the aim is to stretch the foot into the directly opposed position. The most common type is equinovarus and we will make our remarks for such a case. In the mild cases simple stretching several times a day may be sufficient. In more severe cases it is necessary to stretch the foot and maintain it in the over-corrected position. Plaster-of-Paris is preferable to adhesive plaster as it maintains the position better and is not so liable to cause skin injury. One must be careful to avoid a tight plaster and at the same time to have one that can not be kicked off. The plaster should be reapplied every week. At each reapplication the foot is stretched and further correction should be obtained. This is continued until the foot remains in the over-corrected position. Then the plaster may be omitted and the foot held in an over-corrected attitude with adhesive strapping and then manipulations. As the child begins to walk we may have the shoes altered, by raising the outer border for equinovarus, etc. The patient must be watched for a long time. If there is any sign of recurrence, treatment should be reinstituted.

In older or relapsed cases the same method may be tried but these and the most serious cases may need operation such as wrenching, fasciotomy, tenotomy, capsulotomy, wedge, astraglectomy, etc. Untreated cases in older children or adults are difficult and results can not be expected to be so good.

*Congenital Dislocation of the Hip*—Congenital dislocation of the hip may be diagnosed at birth but usually is not found until the child begins to walk. Then the parents notice that there is a limp and an exaggerated lumbar lordosis. I can not say what the result would be in cases diagnosed before walking as we do not see them but it is my belief that they could be very easily reduced and in many cases would stay in place without any plaster or other support.

In the usual case we start treatment when the baby is trained sufficiently to dispense with diapers for in the use of plaster it is essential that they should not be wet. The chances of reduction are very good from this time up to about seven years. After seven we can rarely reduce a dislocated hip without an open operation. In all cases, however, we can usually determine the outcome, for if the head of the femur is not too high and if there is a good acetabulum we may expect to get a cure.

The common variety of dislocation is the one in which the head of the femur is above and behind the acetabulum and the treatment outlined here is for this type of case. Other forms of dislocation require special treatment. Let us consider a case of the most frequent sort. I will not go into the details of the operation but will describe the treatment briefly. The child must be anesthetized sufficient for complete relaxation. The hamstrings, adductors and flexors are stretched and the hip manipulated into place. A plaster spica is then applied to hold the hip in place, thus usually being with the thigh rotated outward, abducted and hyper-extended into what is frequently called the "frog" position. The after treatment consists of maintaining the reduction with a change of plaster every six or eight weeks, each time bringing the thigh down a little toward the normal position. In the average case the treatment covers a period of about nine months.

If a hip can not be reduced in two or three attempts or if it can not be held in place after adequate reduction it is best to let it wait until the patient is a little older and then reduce it by an open operation. Such cases will usually show a shallow acetabulum or one filled with connective tissue or a so-called hour-glass constriction of the capsule.

I have endeavored to cover a lot of ground in a short time and have tried to outline the treatment of these congenital deformities in such a way that it would be of interest to all. I am of the opinion that we can all get a great deal more out of our County Medical Society meetings if we can take up subjects that will not be too special, and that can be discussed by all of the members.

## INFANT FEEDING

By RALPH SHELDON, M D

LYONS N Y

I HAVE been asked to read a paper on infant feeding, the time allotted me being twenty minutes. No living person can write any kind of a paper on infant feeding and only be allowed twenty minutes. It is a subject which covers a lifetime of a physician, and at the end of that time there is much for him to learn.

I am not giving you gentlemen anything new in the line of infant feeding but rather to point out possibly where many of us fail in the caring for our babies. The fault of most physicians in the care and treatment of infants, especially those in the rural districts, is that they do not spend enough time in obtaining the history of their case and thoroughly looking over their patient. They are not careful enough in writing out formulas for mothers to follow, but simply give directions and leave it to the mother's memory to prepare. Thus in a few days the patient is brought back reporting "no improvement."

To me the greatest measure of success in feeding bottle-fed infants, one must pay attention not only to the minutest details of the infant's life but also to the most careful carrying out of all directions in connection with it. You frequently hear the complaint that mothers will not follow the directions. I believe when this is so, quite frequently the trouble lies with the physician. It is an art to take a good history and when one does take a complete history he is familiar with all of the details of feeding and thus inspires confidence.

It is almost impossible to get a correct idea of symptoms and existing conditions from the voluntary information of any mother, and it is left to the physician to tactfully obtain from her the information necessary for successful treatment of his case. It is quite necessary to ascertain the number of children born to the mother, how many living and if any died in infancy to ascertain cause of death, for oftentimes those dying during the bottle period has a direct bearing upon the prognosis of the individual case.

Then comes the question of how long the infant has been breast fed and with what success, for oftentimes a breast fed baby is not obtaining the proper nourishment and is becoming a weakling.

If a bottle baby, a knowledge of the composition of the food used is of the utmost importance in prescribing a new food for an infant.

If food containing cow's milk has been given it is very necessary to guard against giving too large an amount of it and against too rapidly

increasing the same. The same is also true in the use of sugar.

To get the information relating to previous foods it is generally necessary to ask many questions. To the first question asked, What are you feeding the baby? The answer will be usually cow's milk, barley gruel or some proprietary food. It is advisable in such instances to ask, Tell me just how you make this food? It is an exceptional mother who will explain in detail the making of the food and the exact amount of each ingredient used.

After having ascertained the kind of food being taken the next step is to find out the quantity given at each feeding and the interval at which the infant is being fed.

There is a great diversity of opinion as to the intervals of feeding, but I believe that the better men have come to the idea that a three hour feeding with one feeding at night is the best for the infant, although under some conditions a two hour feeding is necessary.

One should be very particular as to the inquiry regarding the condition of the bowels and whether the baby is vomiting. It is oftentimes very hard to obtain this information, as invariably the mother will say, "The bowels are all right and that the baby vomits." That may mean that the baby has only vomited once during the day which is not of any particular moment and bowels moved but once.

One should ascertain and be particular as to the amount of sleep which the child obtains, both during day and night. Also as to whether the child is gaining. The latter is of great importance as it notifies the physician as to the health of the child. The normal infant usually doubles its weight in six months, and trebles it in one year. The loss of weight of an infant after birth should be regained by the end of the second week, and the gain from then on up to six months of age should be from four to six ounces a week.

Do not neglect taking temperature. Oftentimes you are told that the baby feels warm. I have known physicians to dispute the mother simply by placing their hands on the head of the child. No one can tell whether a child has fever or not in that manner.

The examination of the abdomen is of great importance. Invariably infants who have been improperly fed come to you with a marked abdominal distension, and one of the first indications of the improvement of the child under the proper dietetic treatment is a decrease in the distension. A sunken abdomen is usually an in-

dication of a severe or prolonged diarrhoea or a long period of under feeding

When it comes to the proper food for the feeding of a baby, one is oftentimes in a quandary what to do, for there is one set of men who believe, and all of them headliners in their specialty believe, in feeding only modified cow's milk. Another, equally distinctive, are believers in the feeding of unsweetened evaporated milk, and then there is the new set just coming into prominence who believe that is nothing better or quite so good as the feeding of lactic acid milk, or lobbered milk.

Whatever form of feeding you prescribe it must contain three main points. First, it should contain the proper elements to maintain nutrition and to allow growth. Secondly, it should be digestible, and third, it should contain the proper quantity of food, which is best estimated by caloric standards.

The ideal bottle food would be the one that imitates breast milk and would therefore contain three to four per cent of fat, six to seven per cent of sugar and one to two per cent of protein. Such a food when made of cow's milk is not well borne except by infants with the strongest digestive capacity, and therefore it is not practicable to feed these mixtures to difficult feeding cases, and these are the kind of cases that a physician is usually called upon to treat. The reason is obvious. The fat, sugar and protein of cow's milk are of a different kind than those of breast milk.

Since cow's milk contains over three per cent protein and breast milk has only one per cent or two per cent, this element of the food can be made to closely approach breast milk as far as the percentages are concerned, by diluting the milk one-third or one-half. One-third milk will give one per cent protein. One-half milk will give one and a half per cent protein. Cow's milk diluted three times contains only one and a third per cent of sugar, in the form of lactose and when diluted half it contains only two per cent, thus it is necessary to add sugar to bottle feedings in order to bring the sugar content of the food up to that of breast milk. The sugars most often used are cane sugar, milk sugar and malt sugar in the form of maltose and dextrin.

It has been the custom for many years to overcome the acid of the stomach to add an alkali, and the alkali was usually lime water used one ounce to twenty parts of food. Lime water in this proportion will have absolutely no effect upon the acids of the gastric juice, and most pediatricians nowadays use either sodium bicarbonate or sodium citrate or potassium carbonate, two grains to every ounce of milk.

Sugar is the most frequent source of indi-

gestion of any of the elements. It is usually a laxative, though it has not been settled which of the three sugars (cane sugar, milk sugar or malt sugar) is the most laxative. I would advise the use of cane sugar for older infants and those with no intestinal or gastric indigestion. Malt sugar for infants having much intestinal trouble. Milk sugar not at all. Malt soup extracts and wheat flour in those cases that do not do well upon any other kind of sugar. No sugar whatever (temporarily) in infants with diarrhoea or severe vomiting. What is the quantity of sugar that an infant should take within twenty-four hours? A well infant under ten pounds in weight should receive one ounce of sugar in twenty-four hours. A well infant over ten pounds in weight may have one and a half ounces of sugar in twenty-four hours.

This gives in the mixture six or seven per cent of sugar, the same as in breast milk.

The proper quantity of food which supplies the caloric need depends upon the age and condition of the child.

Food may be compared with fuel in a furnace. A furnace requires so many tons of coal to run the engine. An individual infant needs a certain amount of food to use up in heat, energy and growth, and an ounce of milk or an ounce of sugar represents a definite number of calories, the term used to express food value. One ounce of milk equals twenty calories. An ounce of sugar represents one hundred and twenty calories. Babies do not all require the same number of calories. Fat infants over four months of age need forty to forty-five calories per pound per day. The average infant under four months of age and who are moderately thin babies need fifty to fifty-five calories per pound per day. Emaciated babies need sixty to sixty-five calories per pound per day.

As an example—an average infant three months of age weighing twelve pounds, needs fifty calories per pound. Twelve times fifty equals six hundred caloric requirements in twenty-four hours.

The best method of complementing the breast with artificial feeding is to give five or ten minutes feeding from the breast, then complete each feeding with the bottle, using one-third milk and two-thirds water to start with, gradually increasing to one-half milk and one-half water, and if the bowels are constipated add one quarter ounce of sugar in a twenty-four hour mixture, increasing this amount as the weight and condition of the bowels seem to warrant.

From the foregoing it is easy to see that an infant requires a definite number of ounces of milk every day for each pound of weight to

which is added one or one and a half ounces of sugar

A rough rule for estimating the quantity of cow's milk that an infant needs is as follows. The average infant having no digestive disturbances requires in twenty-four hours twice as many ounces of milk as it weighs in pounds provided it can take care of one or one and a half ounces of sugar. Fat, well nourished infants, older than four months, need less than this, while emaciated infants often need much more.

A sour odor of a stool is due to fermentation of the carbohydrates within the intestinal canal. This does not necessarily mean that sugar is being given in too great an excess nor that it is the entire cause of the diarrhoea. The fat may be the original cause of the indigestion and the sugar fermentation a later development. A foul, putrefactive odor like that of decayed meat indicates a putrefactive diarrhoea. The reaction of a stool is of very little importance, except in cases of diarrhoea or in infants who have recently recovered from diarrhoea.

Simple intestinal indigestion is caused by feeding mixtures containing more fat, sugar, protoid or starch than the individual infant is capable of digesting, or by feeding these elements in a form that cannot be digested by the infant.

Indigestion caused by fat is due to the use of top milk or cream. Sugar indigestion is caused by giving an excess of sugar. Gruels are undoubtedly a contributing factor in the cause of diarrhoea in very young infants when given in milk and sugar mixtures.

As to the feeding of dry milk. It is only of value or useful in cases of sickly infants who, while unable to digest milk in other forms, yet oftentimes take dry milk readily and make good progress. The dry milk which has no sugar or any other ingredients is the one best adapted to these cases, especially so where vomiting has been persistent.

The best of the dry milks is Laracen and Caasec.

The remainder of my paper will be devoted to the diarrhoeas of infancy which is oftentimes most obstinate and trying to the physician. The great majority of all diarrhoeas in infancy are the result of one of two things, either the taking of too much sugar or too much fat. I believe it is unwise to treat all cases of diarrhoea by first giving a cathartic. The treatment is usually entirely dietetic. Drugs are of minor importance and even when they are employed a proper feeding must still be instituted. There are usually three different methods of treating diarrhoea and each has its own indications.

The first is giving a protein diet. Stop all sugar, usually feed one-third milk and two-thirds water. The water and milk should be boiled and under this heading cathartics should be avoided. In this type of diarrhoea we get what is known as fermentation. Do not simply reduce the sugar but stop it entirely. You will get diarrhoea in this form as well from under feeding as over feeding. In this type of case barley gruel does not usually act as well as plain water. The boiling of milk and water together, formerly it was believed, was more difficult to digest than raw milk. This is not a fact for it has been proved most conclusively that if properly boiled no tough curds or hard curds form in the stomach and is most easily digested. To properly boil water and milk one should take the proper amount of water, bring it to a boil, then add the milk, stirring constantly until it has boiled three minutes. Then taken from the fire and cooled at once.

The second method of treating diarrhoea is a carbohydrate method. Here we use barley gruel made without milk, thick gruels of various kinds such as corn starch, arrowroot, fed with a spoon. Also gruels cooked with part fat-free milk.

For small infants under four months of age the barley gruel should be made weak. One level tablespoon usually to a quart of water. For the average infants over four months old two to three level tablespoons to the quart of water may be used. Usually in these cases the barley flour is the best to use. Pearl barley, such as Robinson's Pearl Barley, can be used, but it requires three to four hours' cooking instead of the twenty minutes for the flour.

The third method of treating diarrhoea is where we have the mild types of infectious diarrhoea, dysentery, cholera infantum, sugar intoxication and mechanical diarrhoea. In these types of conditions a cathartic should be used, castor oil probably being the best, followed by from twelve to twenty-four hours of starvation, with only water to be taken. After this starvation period a gruel or starch diet should follow.

The differential diagnosis of fermentative and putrefactive diarrhoea is oftentimes difficult. However, it is easy to distinguish either of the two from simple indigestion by the fact that a low grade of temperature usually ranging from ninety-nine to one hundred two degrees F, is present in the fermentative and putrefactive type. The onset of fermentative diarrhoea is more sudden than that of simple intestinal indigestion. The stools of intestinal indigestion have no abnormal odor, while those of the fermentative or putrefactive are either

sour or foul smelling, but in fermentative diarrhoeas we usually meet the foamy stool

Cholera infantum is of a more serious type and probably should come under the head of diarrhoea as no separate classification of bacteria has ever been discovered as its direct cause. Here we have a very rapid depletion of the patient due to diarrhoea and vomiting. Cathartics are of little use, as they are immediately vomited. The washing of bowels by high irrigation should be done. The fluids must be supplied by intravenous or subcuta-

neous injections of saline solution. Give as much as one pint in twenty-four hours. Hypodermic injections of 1-300 of strychnine to 1-50 every four hours. The fever reduced by friction baths and cold applications. Quite often we meet with acidosis accompanying intestinal intoxication, constipation in bottle fed babies, the vomiting of bottle fed babies, the complications of breast fed babies, all of which must be and are met with but time prevents going into same, into their care and treatment of them.

## FRACTURES OF THE UPPER END OF THE HUMERUS\*

By JAMES N WORCESTER, M D,

NEW YORK CITY

THIS subject has been chosen because it has in the past presented a problem particularly of interest from the economical and functional side of the treatment of fractures. The disabilities following fractures or even simple contusions in this region have been out of all proportion to the anatomical changes demonstrable by the present methods of diagnosis in a large percentage of cases. When real anatomical difficulties are added, such as gross malposition of fragments, the problem is still greater.

The shoulder joint is a very complex mechanical problem. It offers in its normal state an extreme range of motion, every one of which motions is of great value in the ordinary pursuits of daily life. When any one of these is limited the disability occasioned seems to incapacitate the individual more than a similar degree of limitation in other joints.

The lines of fracture commonly met with fall into the following groups:

1 Anatomical neck. In my experience, not at all common. The head of the humerus severed from any muscular control may assume any position even turning completely around.

2 Epiphyseal separation.—The same factors are present as in the preceding fractures.

3 Surgical neck.—In this fracture the upper fragment is controlled by the predominating muscles attached to the greater tuberosity and if completely separated from the shaft assumes the position of external rotation and abduction. The lower fragment, under the muscular control of the pectoralis major, is adducted and internally rotated. Any degree of deformity may exist, varying from the so-called "impacted fracture" in which there is no apparent rotary displacement, to that in which the upper

end of the lower fragment is displaced markedly inward and the shaft of necessity rotated internally. However, a careful study of the so-called "impacted fracture" of the surgical neck of the humerus will reveal the fact that stereoscopic X-ray plates show that the head of the humerus is most often in a position of external rotation while the shaft is in internal rotation, for the first X-ray pictures of shoulder fractures are practically always taken for diagnostic purposes with the arm in an adducted and internally rotated position. Union with this altered rotary deformity explains the very common limitation of external rotation. In other words this means that any impaction which occurs is a result of continuance of the trauma after the fracture has been caused and that a rotary deformity is present.

4 External tuberosity.—This may be associated with a fracture of the surgical neck or an independent lesion. In either condition the external rotators of the shoulder control this fragment, and this of necessity is pulled outward.

5 Fracture associated with dislocation. Any of the above fractures may be complicated by dislocation of the head of the humerus.

It is obviously impossible to deal in a paper of this scope with all of the complications concerned in fractures about the shoulder joint. The one object is to attempt to bring the complicated cases into the anatomical possibility of being treated on the same principles as the uncomplicated cases.

This comes down to one common principal. The fractured surfaces of the two fragments must be brought into contact. In the fractures of the anatomical neck and epiphyseal separations, if the lower controllable fragment cannot be put in a position which brings about this result, operative treatment is indicated.

\*Read at the Annual Meeting of the Medical Society of the State of New York at Rochester April 22 1924

with a suture of the fragments to maintain the contact in the proper position. The same is true of the fractures complicated by dislocation of the head of the humerus.

Of the fractures of the upper end of the humerus those having the line of fracture passing through the surgical neck either involving the separation of the greater tuberosity or not, are by far the most frequent. The other complicated fractures having been brought into a condition where the same mechanical problems exist can be treated on the same basis.

The routine treatment as originally proposed by Dr. Joseph A. Blake, in 1916, is based on the following principles:

1. That in the fractures of the surgical neck the upper fragment is almost invariably externally rotated and abducted. This fragment is uncontrollable and the lower fragment must be brought into the same line of rotation and axial deviation.

2. That when a fracture of the greater tuberosity is present this fragment must be externally displaced. If it heals in this position the power exerted by the short external rotators must of necessity be very limited. Therefore, the lower controllable fragment must be brought into external rotation.

These two factors explain the disability present in almost all of the fractures about the shoulder joint treated by methods, which do

not take into consideration the position during treatment, of abduction and external rotation. It has been found that this disability is the one which requires the long period of after treatment. When this position is maintained from the start, it has been my experience, that the natural gravity of the arm furnishes the mechanical forces necessary for the return of the other motions, i.e., internal rotation and adduction.

The maintenance of the position of external rotation and adduction can be maintained by two methods:

1. Immobilization, by plaster. This presupposes the fact that apposition of the fractured surfaces can be accomplished by traction and manipulation. The advantage of this treatment lies only in the maintenance of a proper primary position and possibility of a certain amount of ambulatory freedom. The disadvantages of this so-called immobilization treatment are, that very few people would care to follow their ordinary pursuits with the heavy plaster encircling their chest and with their arm in the required position. Massage, physiotherapy, active motions of the other joints are impossible. A prolonged after treatment to restore the muscular power is still necessary, and in my experience the total period of disability is prolonged over the second method proposed.

FIG. 1 Traction and suspension by Hennequin Band.

FIG. 2 Traction and suspension by means of adhesive plaster

FIG 3 Showing application of Hennequin Band for traction

FIG 4 Illustrating traction and suspension with arm in extreme abduction and external rotation.

FIG. 5 Convenient apparatus for obtaining traction

2 Treatment by the traction and suspension method. The theory of this has been so fully described and its application can be so much better explained by illustration that these two factors will be passed over very briefly and a summary of the results obtained and advantages from a functional and economic standpoint emphasized.

The method necessitates a confinement to bed of twenty-eight days. The apparatus necessary is not extensive and should be at the disposal of anybody treating fractures, and especially available in any hospital. A sense

of the mechanical problems involved is much more important than fancy apparatus.

From the theoretical standpoint the one main consideration is that of bringing the lower controllable fragment into line with the upper uncontrollable one, by traction in the proper line, and at the same time keeping it in the same position of rotation. This necessitates, of course, a portable X-ray apparatus, to check up on these factors. When this reduction has been accomplished, as is usual in the first 48 hours in fresh fractures, not involving the complications mentioned in the first part of this paper it is possible to institute early mo-

with a suture of the fragments to maintain the contact in the proper position. The same is true of the fractures complicated by dislocation of the head of the humerus.

Of the fractures of the upper end of the humerus those having the line of fracture passing through the surgical neck either involving the separation of the greater tuberosity or not, are by far the most frequent. The other complicated fractures having been brought into a condition where the same mechanical problems exist can be treated on the same basis.

The routine treatment as originally proposed by Dr. Joseph A. Blake, in 1916, is based on the following principles:

1 That in the fractures of the surgical neck the upper fragment is almost invariably externally rotated and abducted. This fragment is uncontrollable and the lower fragment must be brought into the same line of rotation and axial deviation.

2 That when a fracture of the greater tuberosity is present this fragment must be externally displaced. If it heals in this position the power exerted by the short external rotators must of necessity be very limited. Therefore, the lower controllable fragment must be brought into external rotation.

These two factors explain the disability present in almost all of the fractures about the shoulder joint treated by methods, which do

not take into consideration the position during treatment, of abduction and external rotation. It has been found that this disability is the one which requires the long period of after treatment. When this position is maintained from the start, it has been my experience, that the natural gravity of the arm furnishes the mechanical forces necessary for the return of the other motions, i.e., internal rotation and adduction.

The maintenance of the position of external rotation and adduction can be maintained by two methods:

1 Immobilization, by plaster. This presupposes the fact that apposition of the fractured surfaces can be accomplished by traction and manipulation. The advantage of this treatment lies only in the maintenance of a proper primary position and possibility of a certain amount of ambulatory freedom. The disadvantages of this so-called immobilization treatment are, that very few people would care to follow their ordinary pursuits with the heavy plaster encircling their chest and with their arm in the required position. Massage, physiotherapy, active motions of the other joints are impossible. A prolonged after treatment to restore the muscular power is still necessary, and in my experience the total period of disability is prolonged over the second method proposed.

## OUR PRESIDENT

What is the ideal that you think the President of the Medical Society of the State of New York should be?

Each of us sees another through our own eyes, and interprets his character and peculiarities in terms of our own. The editorial "We" passes an editor's judgment on the President and compares the work of the presidential office with that of the editor's sanctum.

It is our editorial duty to make ourselves familiar with the inner workings of the State and County Medical Societies, but our duty is done when we have recorded conditions and expressed our opinion of them. The President must get more information than will be revealed to

us, and in addition he must take another big step and secure action based on that information.

We are expected to discern the signs of the times, and know what other medical societies and health organizations are doing, in order to judge their adaptability to our own societies. If we make a fanciful suggestion, no particular notice is taken of it, but let the President make a miscalculation and gravely put forth an impractical suggestion, and then see what the doctors say about him! The President is denied the editor's prerogative of license in speech, and must weigh his silver words against a standard of golden silence.

Publication days come round to us with a

FIG 6 Hand Rest. Strips connecting round bar with spreader are made of elastic.

tion in the shoulder joint, as well as in the elbow joint. The application of heat and light massage may be started very early and the atrophy of the deltoid, produced by the stretching of this muscle in the treatment of fractures of this region in an adducted position, is avoided.

Union is, as a rule, present much earlier than in any other form of treatment. Twenty-eight days has through experience, been almost arbitrarily set for the removal from the apparatus.

At this date the shoulder presents in most cases a complete range of passive motion. Active motion is limited only at this period by a moderate amount of muscular weakness, and is quickly regained by systematic exercises.

The result has been that in cooperative patients the return to their previous occupations have been uninterrupted by a long course of treatment. The ordinary pursuit of their work unless it is of the heaviest type is an advantage.

The routine treatment of the uncomplicated cases has been as follows:

- 1 A careful X-ray study, insisting on stereoscopic plates.

- 2 The application of traction and suspension in a position of external rotation and abduction, the degree of both of these depending on the mechanical problem involved. The traction used is usually eight pounds and is applied through adhesive straps placed on both sides of the arm with the elbow flexed at right angles and the forearm suspended also by adhesive straps. The arm above the elbow is supported by a sling, balanced by weights as is also the forearm. This is modified in many ways as is shown in the slides to follow.

In the fresh cases the position of external rotation and abduction is assumed as soon as possible. In the cases over 48 hours old, it is often inadvisable to attempt this and the position desired must be reached by more gradual means. In the cases in which the lower fragment is displaced inward, it is frequently necessary by traction to pull this fragment down before the position of abduction can be reached. The ultimate aim in all cases is, however, to reach a position of abduction and external rotation as soon as possible. This is maintained through the whole treatment.

Active motion is encouraged from the start. This has in no case interfered with union, but has, on the other hand, seemed to hasten it.

The after results have been almost without exception good, even when anatomically perfect alignment has not been secured. The maintenance from the start of the position which gives the shoulder joint its maximum range of usefulness, and which when lacking, gives it its greatest disability, seems to be the object sought for, and the traction and suspension treatment accomplishes this.

## MONEY RAISING

We recently ran across an advertisement in a health journal in which a firm offers to raise money for hospitals by correspondence "at less cost than by any other means." We know that the firm can do what it says it can do. It has found that a certain number of form letters, sent to a certain selected list of business men in a town, and followed up by a certain number of reminding letters, will produce a certain amount of money. You turn the crank of the machine and the system does the rest. The organization is entirely impersonal, and is run by strangers. Lists of business firms, tax books, church rolls, every list that is readily available are used. Many mistakes and duplications are made, many good givers are overlooked and many are dunned twice and three times. The final result looks good, and the hospital managers are relieved of an immense amount of personal work and worry.

Now let us look on the opposite side of the picture. These canvassers are like strange revivalists who turn a town upside down for a week or two and then leave all the unstable converts on the hands of the local pastors and church officers.

A local hospital depends on the good will and support of all the people in a town. It is not

sufficient that "business" methods are followed and enough money raised to pay running expenses. A store can prosper if only twenty-five per cent of the people of a town patronize it. A politician will prosper if only fifty-one per cent of the voters support him. The business man and the politician can ignore the minority. But a small hospital prospers only as practically all the people take an interest in it.

Each of us gets out of a thing just what we put in it, and very little more. Hospital managers may hire strangers to canvass a town in an impersonal way, but the personal touch is what counts for real success. If the managers do not work for a hospital, neither will the people.

There is a system by which a firm will supply an expert or two and the materials, and then the local people do the canvassing by personal solicitation. This method not only raises the money but it enables those interested in the hospital to make friends for the hospital and to explain its work.

We are impelled to write these thoughts by the observation of the workings of an impersonal canvass. We prefer the personal system.

F O

## FEET AND BACKS

Two of the most common conditions from which people seek relief are painful feet and backache. Doctors don't like to treat these conditions because they say "Folks will not do as they are told." Rest is usually advised, and it will nearly always relieve both painful feet and backache, but of course that is a prescription that most people will not take.

Rubbing and massage and manipulations and baking will usually relieve both conditions, but few doctors care to give the treatments, and so the patients go to chiropractors, who are quite likely to give them relief, at least temporarily. It is just these patients that bring credit to the quacks and discredit to the doctors who fail to treat them.

What are the conditions that cause foot pains? They are those which are associated with flat feet, fallen arches, muscular flabbiness, overweight, and other conditions which bring an unusually severe strain on the feet. Foot pain may be compared to an eye pain that is caused by strain of the eye muscles. It is present when the organs are used, and absent when they are rested.

There is nothing mysterious in foot pains. The parts can readily be seen, and their functions tested. Their treatment is standardized and any physician can readily learn both to diagnose and to treat the condition.

The tendency to painful feet can be recognized

at an early age. The report of the examinations of school children in New York City shows that from five to ten per cent of all children have serious foot conditions that vary from "wiggly" ankles, to complete flat foot. These children will suffer from painful feet when they do work which requires them to stand or walk.

The detection of these foot conditions in school children is easy. The treatment is equally simple and consists in exercises to strengthen the muscles that hold the arch of the foot tense and rigid.

When we consider the causes of backache, the condition is not so simple, although strains of ligaments and muscles are the usual causes. Orthopedists are now recognizing the fact that trouble with the sacroiliac joint is frequent, and when this trouble is present, chiropractic treatment aggravates the condition.

So long as little was definitely known regarding the cause and treatment of foot pain and backache, physicians were excusable in failing to take any deep interest in the cases, but now that orthopedists are able to relieve the conditions, it is time that general practitioners should take up their study, and give the patients the relief to which they are entitled. If physicians do not do this, are they practicing modern medicine? One of the best ways of dealing with chiropractors is that physicians give satisfaction to the cases that leave the doctors and go to chiropractors. And why do they leave the physicians? The patients

whirr and often find our mind as blank as the paper before us. But somehow, one word suggests a thought that calls for more words, and getting started seems to be our hardest task. And then we still have the comforting assurance that we will get another chance at expression when we read the proof.

Appointments come thick and fast to our President, and he is even denied the privilege of sitting on the back seat and enjoying the show. He must sit on the platform and look interested in the speaker while he wonders what possible thing he will be expected to say. But a proper shyness pleases an audience immensely, and a studied search for the appropriate word gives an impression of numberless others in the rich storehouse of the brain. It is not so much what the President says off-hand, as the impression that he is suppressing much more that he could say if he were less considerate of his audience.

The editor is constantly learning something new. He cannot live in the past or repeat him-

self, but accurate information is the meat and drink on which he thrives and grows. The President can neither bind himself to conventionalized ideas, nor shut his eyes to evolving conditions. He will be judged by the items of progress and growth which he has added to the life of the Society.

We, the editor, must do our full daily stint promptly, fearlessly, conscientiously, without undue timidity lest our hat may not be on straight. We get our ideas from others, but their clothes are ours.

The President has a huge array of daily tasks to perform, and many excellent advisors to give him new ideas, but action is his.

We started out to be impersonal and to compare the practical editor with the ideal president. We end by being personal and confessing that Dr. Owen E. Jones supplied the model and the inspiration on which we based our impersonal picture of the presidency. F O

## THE WEEKLY JOURNAL

This issue of the JOURNAL is the last of the weekly numbers that have been planned for the year 1925. We have printed fifteen weekly issues this year, while last year we issued twelve.

We will mail the May number on May 7th, one week earlier than usual on account of the annual meeting which will fill the following week. We will issue the succeeding numbers as near the middle of the month as possible.

We have had our ear to the ground in an honest effort to find out how the members like the JOURNAL. Almost the only criticism that we have heard was that the JOURNAL had too much legislative matter in it. Our reply is that the JOURNAL has been issued weekly in order to carry full information about legislation in Albany. We wish we did not have to put all the legislative news into a few issues, but we have to adapt our plans to those of lay legislators.

Some think we could compress and condense the legislative news. Yes, we could if we actually had a week to edit each issue. But here is the schedule which we follow. Friday noon, adjournment of the Legislature for the week. Saturday afternoon late, receive the official report of actions taken on all bills. Sunday, spend the day checking up the bills and the previous comments in the JOURNAL, dictating new comments and writing editorials,—all of which must be ready for mailing that evening. Monday, the account is received in the editorial office and prepared for the printer, a copy is sent to the printer. Tuesday,—some galley proof is received from the printer, and used in making up some of the pages of the week's JOURNAL. Wednesday the

morning is spent in the printer's office making up the pages of the JOURNAL, reading proof, and making indexes. About one o'clock the printer says "We positively must put the JOURNAL on the press at four o'clock, and there is no time for you to make any more changes." Thursday, we recall a lot of good things which we have failed to say as well as we might, and ruefully consider half an article which had been cut in two owing to lack of space. Friday noon, we receive the first copies off the press, and see our editorial mistakes glaring at us.

The point is that we have only one day in which to get out our legislative matter. So far as the department of legislation is concerned, we work as we would on a daily newspaper.

But don't let anyone get the idea that we are complaining. On the contrary we thoroughly enjoy the hurry and the rapid writing, and the sense of doing things. We like to try out ourselves and see what we can do. We find that we can write an editorial in the printer's office and have it back in type form in half an hour,—and that is as quick as it is done on a daily paper during rush hours, and then the final thrill comes when a medical friend tells us how that editorial showed careful thought and preparation.

We flatter ourselves that our weekly issues were better than those last year, and we are so egotistical as to feel that next year's will be still better. Possibly we may even try to do the impossible task of preparing a three-page legislative summary that shall contain every detail about every medical bill. F O

# LEGAL

By GEORGE W. WHITESIDE, Esq  
Counsel Medical Society of the State of New York

## PROTECTION AGAINST LAW SUITS

The past twenty years have worked great changes in the political, economic and social life of this country, during this time our capacity to assimilate vast hordes of European immigrants has been taxed to the breaking point. The strangers in our midst have come here seeking the land of opportunity and many of them have brought energies, traits and qualities which, when properly assimilated, will be of permanent value to the land of their adoption. But they have brought, also, standards and traditions, conceptions and points of view quite alien to our American teachings. In no part of the country is this more apparent than in the great city of New York, the counties of Long Island, Westchester and Rockland, which comprise what is known as the metropolitan district.

In this area are splendid hospitals, completely equipped and manned and rendering a scientific, diversified and conscientious service to mankind. No other section possesses a more conscientious, better trained, more generous or public-spirited class of professional men than those who practice medicine in this territory. Nevertheless, within the past four and one-half years in this metropolitan district, where but sixty-one per cent of the State Society's membership practices, there have been instituted five times as many malpractice suits as were brought in the remainder of the State. The damages claimed in actions now pending against doctors in this district aggregate the staggering total of upwards of two and one-half millions of dollars. Those who are engaged in the alleviation of pain and suffering, in the care of the injured and the sick, and whose time, whose skill and whose knowledge are so largely given gratuitously to that part of mankind which is unable to pay for the services received, find themselves engaged in what may be truly termed an extra hazardous profession.

Large numbers of suits are instituted in this district by patients who have been the recipients of charity, who do not speak English, and who are wholly unacquainted with the ways, standards and traditions of the country which they have sought as a refuge from the oppressions and injustices of Europe. Many of these cases are devoid of any merit whatever. Some of them are built up on testimony quite incapable of withstanding the scrutiny of a court of justice. Yet all of these assaults upon the good name of some doctor present hazards and risks fully understood and appreciated only by those doctors who have

been sued in malpractice suits. Quite often the case, wholly destitute of merit, presents the gravest cause of concern to the doctor and to your counsel who defends him. Sometimes these cases rest upon the faulty understanding of the English language by the plaintiff who has lately come to these shores or who, having been here a long time, has never learned to speak our language. Sometimes these cases are founded upon testimony largely fabricated by those who have failed to assimilate the standards of decency, fairness and good faith which underlie American institutions. In such cases the capacity of your counsel to unearth and expose either ignorance or fraud is the sole reliance of the honest medical man. Those for whom most has been done often become the most unreasonable critics.

In a case recently tried in New York City a woman had been the recipient for many weeks of the skill, care and attention of the doctors and nurses of one of the best equipped metropolitan hospitals. She was suffering from arthritis. After she had been treated for many weeks, had been the subject of the best possible attention, had had innumerable analyses made, had been the beneficiary of X-ray diagnosis, she contended that one of the doctors on the staff came into her room and by a forceful manipulation of her leg, dislocated her hip. Only through the weapon of cross-examination was it developed that the dislocation claimed did not occur until many months after the supposed manipulation of the defendant doctor, and that in the meantime her limb had been massaged and manipulated by a masseur. At the close of the plaintiff's case the judge dismissed the complaint. Yet this action consumed four days of the defendant-doctor's time and presented a serious risk and danger both to his good name and pocketbook.

In no section of the State are there more lawyers willing to take cases against doctors, in no section of the State are there more potential plaintiffs, in no section of the State are there more doctors of a certain type who are ready to express an opinion of condemnation upon mere slender and inadequate premises, than in this metropolitan district.

No medical man thoroughly appreciates the hazards of his profession until he has been sued. Your counsel has observed the psychology of countless doctors who have been forced for days at a time to drop their practice and to hear themselves presented in court as the villain of the

often say, "The doctor did not understand my case" Let the doctor take the time and trouble to understand those cases Let him take an interest in the prevention of the trouble by attention to school children, both in the school and in his office If doctors generally do this, they will retain a large percentage of the cases that now go to chiropractors

We believe that the subjects of painful feet and backache are neither too difficult for a general practitioner to understand nor too unimportant and impractical to be ignored We have asked an orthopedist to prepare a series of simple articles on these subjects to be published next summer or fall  
F O

## CHIROPRACTIC LITERATURE

The chiropractors are using wise tactics to promote their own interests They are capitalizing remarks that were made at the hearing before the Legislative Committees on Public Health on March 4th, and are frequently inserting letters in the daily press calling attention to alleged errors on the part of medical men Physicians should consider these arguments of the chiropractors in order to meet them effectively

The New York *Herald-Tribune* of March 25th, contains the following statement from Lyndon E Lee, President of the New York State Chiropractic Society

"We are deeply impressed by the statistics from the Massachusetts General Hospital, published by Dr Richard C Cabot, in which he says that medical diagnosis varies in error from 30 to 80 per cent in ordinary, every-day illnesses, and the general average of error is in excess of 50 per cent In the interest of public health and the efficiency of our practitioners we have no desire to employ methods as fallible as these

"The chiropractic schools teach a thorough course in chiropractic analysis, which is a system of arriving at the cause of disease and its character through a knowledge of the nerve centers

involved, as well as the general symptoms considered by the ordinary physician

"'Physician' feels deeply concerned for the public health if chiropractors are allowed to treat contagious diseases May we direct attention of this doctor to the fact that during the influenza epidemic of 1920 the Board of Health statistics show the death loss of the medical men to have been one in every 17 cases, while the chiropractor lost only one out of every 886

"The plea of 'Physician' that the state 'make chiropractors show their qualifications in the same way that physicians have shown theirs' is made somewhat ridiculous when it is remembered that at the public hearing on the chiropractic and medical bills at Albany this same argument was advanced by a medical advocate and was met instantly by an offer on the part of the chiropractors to submit at once to examination under the State Medical Board if the medical representatives would do likewise The argument ended abruptly with a flat refusal on the part of the learned medicos"

Think over these arguments, and prepare your answer You will run across some chiropractic admirer who will use these arguments Prepare yourself to meet them  
F O

## MEDICAL LANGUAGE

One of the duties of an editor is to edit The word edit carries a variety of concepts By the contributor it is often interpreted as a deliberate attempt on the part of the editor to change the meaning of his sentences—and that is our intention when the contributor says what he does not mean

Sometimes our editing seems to our contributors to be an attempt to embellish their plain statements with grammatical flourishes, and they are sometimes right We wish every contributor would recall that English grammar exists in order to render language clear

Sometimes our contributors accuse us of "stringing out" their thoughts Sometimes we

add a few unessential details or comments just to lend attractiveness to dry, dull, uninteresting statements

We try to make the notices of meetings interesting, and in order to do so, we frequently have to do a lot of editing—usually in the way of additions of interesting details

We sometimes write out a doctor's abbreviations, when we can, but now and then we run across a poser If our readers cannot tell what the abbreviation means, they ascribe the obscurity to the editor's poor proof reading, and we accept the charge rather than expose our ignorance When we receive an obscure, ungrammatical announcement, we accept the implied compliment that the editor can do anything  
F O

# State Department of Health

## ADULT DIES OF UNCOMPLICATED MEASLES

A supplementary report on a measles death recently received by the Division of Communicable Diseases stated that the patient, a young woman of 22, was in excellent health up to the time of her infection which was contracted from exposure to the case of her brother. According to this report, the rash appeared one day after the first symptoms and she died three days after the appearance of the rash. The temperature when first seen by the physician was 102, but diminished to 99  $\frac{4}{5}$  on the morning of the day she died. The physician stated that the patient did not complain of feeling bad in any

way except itching of the skin until the first symptoms subsided, and felt in good condition up to two hours before death. The physician arrived about 11 P. M. and found her in a comatose state—temperature 108, pulse 150, lungs clear, no complications except that the rash had taken on a hemorrhagic appearance, the patient died about twenty minutes after the physician arrived. A peculiar feature of the case was that the patient had expressed a dread of the disease during her brother's illness, although there was no apparent reason why she should not make a good recovery.

## ADULT PARALYZED FOLLOWING DIPHTHERIA

One of the District State Health Officers was recently called to see a patient, age 36, who is a Russian. This man gives a history of having had a sore throat about the tenth of January, at which time a physician treated him for tonsillitis. Two weeks later he called a second physician on account of paralysis of his arms and legs. The second physician took a culture of the throat, which was found to be positive for diphtheria. The patient was taken to a hospital and had been there up to the time the last report was made

to the Department. It was stated that he still has wrist drop of the right wrist and considerable paralysis of both arms and legs and is unable to be out of bed. On March 25, positive cultures were still being obtained.

An interesting point in this case is that the patient owns the house in which two children died from diphtheria in January and February. One of them died from diphtheritic paralysis. The man probably received his infection from this family.

## DEATH REPORTED FROM MUMPS

The death of a girl baby, eight months old, from mumps, was recently reported from Gouverneur. On March 21, this child was suddenly taken ill with fever and vomiting. The next morning the left parotid gland began to swell. In the evening the mother noticed that the swelling over the parotid was dusky in hue. The physician who called found the temperature 102, respiration 40, heart too fast to count. The legs were reported to be purple in places, but there was no cough or respiratory symptoms.

The District State Health Officer was called in consultation in this case two days later. At this time the temperature was 101, respiration 45, pulse imperceptible, heart action distinct and

regular, but so rapid that one could not attempt to estimate the rate. Pupils were normal, reflexes equal but slow, no stiffness of neck, face slightly flushed, skin over the parotid was purple, the color disappearing on pressure, both legs were dusky purple, which would disappear on rubbing, no purpuric eruption, throat negative, abdomen soft. The child died shortly afterwards.

The District State Health Officer feels that the reported cause of death, namely mumps, was the true one in this case, as the whole family had the same disease and none of them had influenza. He believes that the mumps infection may have been sufficiently virulent to set up a general septicemia.

## DEATH REPORTED FROM ACUTE EXACERBATION OF MASTOIDITIS DUE TO PARA-TYPHOID BACILLUS

The patient in this case was admitted to the Vassar Hospital, Poughkeepsie, with an acute ear condition, para-typhoid bacilli were found in the

discharge from the ear, blood showed a negative Widal and there was no history of para-typhoid fever. The patient was a man, age 38.

piece, watching with chagrin, amazement and concern the unfolding of their alleged shortcomings. The possession of insurance, under such circumstances, in addition to the knowledge that their rights will be safeguarded in court, is a source of assurance, confidence and consolation which only those who have been sued fully understand and appreciate.

Despite all this, the amazing fact remains that only forty-nine per cent of the doctors eligible for our group plan of insurance within the metropolitan district have availed themselves of its benefits. It is an amazing fact that 3,241 doctors

in this territory are not carriers of the group insurance protection. After the action has been begun it is too late to procure insurance covering that action. Many doctors who have neglected to obtain the benefits of the plan which the State Society has inaugurated for them, come to us after suit has been brought literally wringing their hands at their own neglect.

The question fairly arises for all doctors, both those with years of experience and those who are just embarking upon their professional career: Is it safe to practice medicine without being insured?

### CLAIMED INFECTION FROM RETAINED PLACENTA

It was charged that the defendant as a physician was engaged to attend the plaintiff in confinement, that he was careless and negligent and failed to use the proper care and skill in his attention to the plaintiff in that he permitted the placenta to remain within the plaintiff for a period of twenty-eight hours after the delivery of her child, and by reason of this fact the plaintiff claimed that the womb, ovaries, fallopian tubes and appendix of the plaintiff became inflamed and diseased and it was necessary that she submit to an operation for the removal of the tubes, ovaries and neck of the womb and appendix, that she was confined in a hospital for about a month and suffered permanent injury by the removal of the genital organs.

The defendant had been the family physician of the plaintiff and had attended her in a previous confinement. In the particular case he attended the plaintiff for about a month prior to her confinement, made urine examinations and gave her the necessary pre-natal care. She resided in a small village about five miles from the defendant's office and the birth occurred in the winter when the roads were rendered impassable by reason of a recent snowstorm. On the day of the birth he went to the plaintiff's home about noon and remained in attendance until after delivery about five P. M. The patient was extremely irritable, the labor being rather difficult, and the physician remained with her for about an hour after delivery and administered ergot. The proper attempts were made by the physician to express the placenta, but without success. Upon examination he found a little contraction at the end of the uterus. He then applied a pack soaked in a lysol solution and left instructions that he would return on the following morning, but to

telephone if anything occurred. About noon of the following day he returned to the patient's home and endeavored manually to express the placenta, again without success. After this attempt he administered ether and with a sterile glove removed the placenta by hand. For the next ten days the patient was seen by the defendant every second or third day and her condition gradually improved until about the tenth day, when she was up and about the house. At about the fourteenth day after the birth she visited the defendant at his office. During this time there was no complaint by the plaintiff. About seven months after this attendance upon the plaintiff by the defendant, he was called to her home, she at that time complaining of distress at the stomach. He prescribed for and treated the condition and made several visits to the plaintiff's home. Nothing further was heard from the patient until the institution of this action about a year and a half later.

It was ascertained that about twenty-two months after the defendant's last visit to the plaintiff, her appendix, tubes and ovaries were removed, due to an inflammatory condition. It was also ascertained that about a year after the delivery of the plaintiff by the defendant, she was delivered of another child and that the operation which plaintiff claimed was due to the alleged carelessness of the defendant in his care of her, was performed about ten months after the birth of this child.

The plaintiff's attorney strenuously sought to procure a settlement of the action, but when forced to trial abandoned the case and the suit resulted in a dismissal of the complaint in favor of the defendant.

of the hospital needs of the country as a guide in future planning and building

Suffolk County has a general hospital in each corner of the County, and a Tuberculosis Hospital near the geographic center. The hospitals are as follows

Name	Location	Number of Beds
South Side	Bay Shore	50
Southampton	Southampton	65
Eastern Long Island	Greenport	25
Huntington	Huntington	35
Tuberculosis Sanatorium	Holtsville	90
		<hr/> 265

The ratio of beds is about two and one-half for each one thousand of population

The Suffolk County Medical Society conducted a confidential study of the management of the four general hospitals, and made the information available to the officials of the hospitals. The studies and comparisons were of great value in improving the economy and efficiency of the hospitals. One hospital reduced its expenses twenty-five per cent as the result of observations of the methods used in the other hospitals

The four general hospitals of Suffolk County are open to practically all the physicians in the vicinity. Two hold regular monthly staff meetings, and conform to the standards of the American College of Surgeons, and the other two are approaching those standards

*Medical Societies*—The membership of the county medical societies on Long Island, and the percentage of physicians belonging to them, are shown by the following table

County Society	Number of Members	Percentage of Physicians
Kings	1,578	60
Queens	249	53
Nassau	154	70
*Suffolk	110	95

\*Exclusive of State Hospital staffs.

Every county medical society on Long Island is active, and is doing original work along some lines. The activities of the Kings County Medical Society are described on page 664 of our last week's issue

The methods of carrying on the work of the three other societies are governed largely by transportation facilities. The public transportation lines run east and west, for New York City is their principal objective. Travel east and west is easy while that of north and south has been difficult. However, the automobile now solves the transportation problem, and the result is that now the meetings are well attended. The meetings of the Queens and Nassau Societies are held in the evening, and a social supper is served

The physicians of Suffolk County meet and

dine together at noon, for distances are too great for an evening meeting

*Queens County Medical Society*—The Medical Society of the County of Queens is undergoing a rapid evolution and development in keeping with the growth of the County. It meets monthly, and the programs of its meetings are frequently on civic topics. The attendance at each meeting is about one hundred. It owns a lot with 200 feet frontage on the Boulevard in Forest Hill, in the center of the County, and is now raising a fund for the erection of a large building which shall be the medical center of Queens County. The building will be of a size sufficient to meet the future needs of the Society, but the rental of the present excess space will be sufficient to provide for maintenance and a sinking fund. It is planned to develop the County Society along the lines of the Kings County Society, and to unify all the medical organizations of the County in the County Society

*The Bulletin*—The Queens County Medical Society has recently established a monthly Bulletin of twelve pages which carries announcements of coming events, and descriptions of previous meetings, and news of medical activities in the County. It is also printing the Principles of Medical Ethics of the Medical Society of the State of New York—an excellent idea, for while physicians know there is a code, they can seldom quote it accurately

The Bulletin carries a few advertisements which are sufficient to pay the printer's bills

*Nassau County Society*—The Nassau County Medical Society holds eight monthly meetings and one social outing each year. The regular meetings are held in the center of the County, and begin with a social supper at about seven o'clock. The programs of the meetings are about equally divided between scientific and civic subjects. The Society has made intensive studies of the hospital needs of Nassau County, and of the management of the work of the Tuberculosis Committee. It has promoted all phases of tuberculosis work in the County, and is now planning a series of teaching clinics in pediatrics and other subjects as an extension of the graduate courses of the Medical Society of the County of Kings

*Suffolk County*—The Suffolk County Medical Society holds only two meetings a year, owing to the difficulties of travel. The County is 75 miles long and 20 wide, and its sections are separated by either broad arms of salt water or immense stretches of poorly roaded woodland. Yet the Society is one of the most active in the State. It has undergone an evolution along unusual lines which may be classi-

# MEDICAL SURVEY

## MEDICAL SURVEY, NUMBER 10—MEDICINE ON LONG ISLAND

**EDITOR'S NOTE** The subjects of Surveys Numbers 8 and 9 have been the two largest counties which compose Greater New York. We have shown that the differences in the Medical Societies of the Counties of New York and of Kings arise largely from the natural evolution of the two organizations. The medical profession of each county of Greater New York forms a natural unit that is surprisingly individual and distinct, but the Medical Society of the County of Kings has a direct and extensive influence on the medical organizations of the other counties of Long Island. The counties of Kings, Queens, Nassau, and Suffolk are therefore closely related medically, and a consideration of this relationship will form a part of this Survey.

The data for this Survey have been derived largely from the same sources as those for the Survey of Kings County. We are also indebted to Dr. Henry C. Courten, President of the Medical Society of the County of Queens, to Dr. Arthur D. Jaques, Secretary of the Medical Society of the County of Nassau, and to Dr. George H. Schenck, President of the Medical Society of the County of Suffolk.

Long Island is 110 miles long and 20 wide. It has an area of 1,373 square miles, and a population of 2,723,764 people, according to the census of 1920, but the five year increase makes the 1925 population over three millions.

The Island is divided into four counties whose population is an inverse ratio to their areas, as is shown by the following table:

County	Area Sq. Mile	Population 1920	Population 1925 Estimated
Kings	71	2,018,356	2,235,886
Queens	108	469,042	578,851
Nassau	274	126,120	175,000
Suffolk	920	110,246	125,000
Total	1,373	2,723,764	3,114,737

*Area and population of the four counties on Long Island*

The distribution of population on Long Island is the direct result of waves of emigration which start from the Metropolitan Center and spread in all directions with a speed which is governed by the facilities for rapid transit. Queens County is rapidly being built up as closely as Kings County. The fringe of dense population is now invading Nassau County, although the most of the County remains rural. Suffolk is entirely rural, half of its area is still unsettled, and the greater part of its population is collected in a fringe of villages along its southern coast line.

**Physicians**—The number of physicians on Long Island and their distribution by counties is indicated by the following table:

County	Number of Physicians	Ratio to Population
Kings	2,631	1 to 835
Queens	472	1 to 1,200
Nassau	154	1 to 1,100
*Suffolk	110	1 to 1,100

\*Exclusive of 37 on the staffs of two State Hospitals.

The physicians on Long Island are fairly evenly distributed according to population, and the average number of people served by each doctor is large as compared with the rest of the State. The population is rapidly increasing, and the doctors share the general prosperity of the Island.

**Hospitals**—Queens County has six hospitals, as follows:

Name	Location	Number of Beds
Flushing	Flushing	120
St. John's	Long Island City	200
Jamaica	Jamaica	140
St. Mary's	Jamaica	90
St. Joseph's	Far Rockaway	100
Queensboro Contagious	Jamaica	50
		<hr/> 700

The proportion of hospital beds in Queens County is slightly over one bed per thousand of population. This small ratio is due to the rapid growth of the County, and the nearness and availability of the hospitals of Brooklyn and Manhattan.

The hospitals are well organized and conform to the standards of the American College of Surgeons.

Nassau has four hospitals as follows:

Name	Location	Number of Beds
Nassau	Mineola	120
Mercy	Hempstead	20
Glen Cove	Glen Cove	30
Tuberculosis Sanatorium	Farmingdale	110
		<hr/> 280

Nassau County has about one and one-half hospital beds for every one thousand of population, but additions which are already planned will double the hospital capacity.

The Nassau Hospital is conducted after the manner of the Metropolitan hospitals. Two internes are employed, staff meetings are held, and the standards of the American College of Surgeons are observed. The Nassau County Medical Society conducted an extensive survey

of the hospital needs of the country as a guide in future planning and building

Suffolk County has a general hospital in each corner of the County, and a Tuberculosis Hospital near the geographic center. The hospitals are as follows

Name	Location	Number of Beds
South Side	Bay Shore	50
Southampton	Southampton	65
Eastern Long Island	Greenport	25
Huntington	Huntington	35
Tuberculosis Sanatorium	Holtsville	90
		<hr/> 265

The ratio of beds is about two and one-half for each one thousand of population

The Suffolk County Medical Society conducted a confidential study of the management of the four general hospitals, and made the information available to the officials of the hospitals. The studies and comparisons were of great value in improving the economy and efficiency of the hospitals. One hospital reduced its expenses twenty-five per cent as the result of observations of the methods used in the other hospitals

The four general hospitals of Suffolk County are open to practically all the physicians in the vicinity. Two hold regular monthly staff meetings, and conform to the standards of the American College of Surgeons, and the other two are approaching those standards

*Medical Societies*—The membership of the county medical societies on Long Island, and the percentage of physicians belonging to them, are shown by the following table

County Society	Number of Members	Percentage of Physicians
Kings	1,578	60
Queens	249	53
Nassau	154	70
*Suffolk	110	95

\*Exclusive of State Hospital staffs

Every county medical society on Long Island is active, and is doing original work along some lines. The activities of the Kings County Medical Society are described on page 664 of our last week's issue

The methods of carrying on the work of the three other societies are governed largely by transportation facilities. The public transportation lines run east and west, for New York City is their principal objective. Travel east and west is easy while that of north and south has been difficult. However, the automobile now solves the transportation problem, and the result is that now the meetings are well attended. The meetings of the Queens and Nassau Societies are held in the evening, and a social supper is served

The physicians of Suffolk County meet and

dine together at noon, for distances are too great for an evening meeting

*Queens County Medical Society*—The Medical Society of the County of Queens is undergoing a rapid evolution and development in keeping with the growth of the County. It meets monthly, and the programs of its meetings are frequently on civic topics. The attendance at each meeting is about one hundred. It owns a lot with 200 feet frontage on the Boulevard in Forest Hill, in the center of the County, and is now raising a fund for the erection of a large building which shall be the medical center of Queens County. The building will be of a size sufficient to meet the future needs of the Society, but the rental of the present excess space will be sufficient to provide for maintenance and a sinking fund. It is planned to develop the County Society along the lines of the Kings County Society, and to unify all the medical organizations of the County in the County Society

*The Bulletin*—The Queens County Medical Society has recently established a monthly Bulletin of twelve pages which carries announcements of coming events, and descriptions of previous meetings, and news of medical activities in the County. It is also printing the Principles of Medical Ethics of the Medical Society of the State of New York—an excellent idea, for while physicians know there is a code, they can seldom quote it accurately

The Bulletin carries a few advertisements which are sufficient to pay the printer's bills

*Nassau County Society*—The Nassau County Medical Society holds eight monthly meetings and one social outing each year. The regular meetings are held in the center of the County, and begin with a social supper at about seven o'clock. The programs of the meetings are about equally divided between scientific and civic subjects. The Society has made intensive studies of the hospital needs of Nassau County, and of the management of the work of the Tuberculosis Committee. It has promoted all phases of tuberculosis work in the County, and is now planning a series of teaching clinics in pediatrics and other subjects as an extension of the graduate courses of the Medical Society of the County of Kings

*Suffolk County*—The Suffolk County Medical Society holds only two meetings a year owing to the difficulties of travel. The County is 75 miles long and 20 wide, and its sections are separated by either broad arms of salt water or immense stretches of poorly roaded woodland. Yet the Society is one of the most active in the State. It has undergone an evolution along unusual lines which may be classi-

fied as 1, group societies, 2, the practice of civic medicine, 3, a periodical news letter, and 4, teaching clinics

Geographic peculiarities have caused the population of Suffolk County to be grouped in four distinct sections, each of which maintains a general hospital. The physicians in each section form a natural group which were brought together through a common interest in the hospital. Out of this association has grown four group medical societies which are practically branches of the County Medical Society. Some of the groups are better organized than others. The South Side Clinical Society is the oldest and best organized, and is composed of the group of physicians who live in the south west corner of the County, and are on the staff of the South Side Hospital in Bay Shore. It has thirty-five members and an average attendance of twenty-five at its monthly meetings. The program of each meeting begins with a social supper at 7 o'clock, which is followed by a scientific meeting.

Other group societies are centered about the hospitals in Southampton, Greenport, and Huntington.

The Suffolk County Medical Society has been active in the practice of civic medicine for many years. It originated and conducted a successful campaign which resulted in the establishment of a county tuberculosis hospital in 1916. It has continuously agitated the establishment of a general county hospital for chronic cases to be built as soon as the needs of the tuberculosis hospital are fully met. It has developed a practical system of field work in tuberculosis, and has been the means of unifying the methods of hospital management throughout the county.

*The News Letter*—The Suffolk County Medical Society publishes an eight-page News Letter each month. This publication is the natural development from small bulletins of information which were sent to the members at irregular intervals. Its object is to carry notices and descriptions of meetings, and to inform the members regarding medical matters throughout the County. Some of the articles are written with the object of having them quoted in the local press, and editors usually consider the contents of the News Letters to be good news for reproduction or comment.

About 300 copies of the News Letter are printed each month, at a cost of about \$250 annually. The publication is sent free to every member of the Society and to a large list of physicians and organizations outside of the County. About half of the dues of the Society are used in producing the News Letter, but the members unanimously desire its continuance.

*Teaching Clinics*—The Suffolk County Medical Society has sponsored a series of teaching clinics for physicians as an extension of the graduate education courses of the Medical Society of the County of Kings. A demonstration course in pediatrics is held weekly in the South Side Hospital at four o'clock on every Tuesday afternoon (See this Journal, April 3, 1925, page 587). Plans are being made to hold similar clinics in other hospitals.

*Tuberculosis*—The official anti-tuberculosis work in Queens County is under the Department of Health of Greater New York, and cases needing hospital care are sent to institutions supported by the Greater City. It also has an active citizens' committee.

Nassau and Suffolk Counties each have a County Sanatorium with about 100 beds. The superintendent of each sanatorium conducts diagnostic clinics and directs the activities of two field nurses. One special feature of the tuberculosis work in each county is that it is done with the cooperation and assistance of the physicians.

The field work of the discovery and visitation of cases is carried on as a medical problem in epidemiology in the same way that outbreaks of scarlet fever or typhoid fever are handled. New cases are sought among those in contact with previously known cases, with the result that the number of known cases per annual death is fully equal to the number discovered by the Framingham demonstration, which has been the best known standard for comparison. The cases are not merely discovered and listed, but the system of visitation and advice is efficient as is shown by the unusual fall in the death rate from tuberculosis.

*Health Departments*—The official public health work in the Counties of Kings and Queens is under the Department of Health of Greater New York City. That in both Nassau and Suffolk Counties is conducted by the local boards of health of its two cities, thirty-six villages, and thirteen townships. The character of the public health work done is as variable as the populations of the units. One village is credited by the 1920 census with a population of three, another with eleven, and another with seventy-one. On the other hand, the township of Hempstead contains 40,000 people, besides 40,000 more in its ten incorporated villages. In general the public health work in the larger units is very well done.

*The Associated Physicians of Long Island*—The physicians of all Long Island are closely associated together by an organization called the Associated Physicians of Long Island. This organization was formed on April 14th, 1898, eight years before the present organization of the Medical Society of the State of New York was perfected. When the Second District Branch of

the Medical Society of the State of New York was organized in 1906, its functions were already being well performed by the Associated Physicians. There has been harmony between the two bodies, the same leaders have been active in both, and still closer cooperation is planned for the future.

The Associated Physicians has a membership of about 1,000, drawn from all four counties on Long Island. About two thirds of the members live in Kings County and one-third in the other three counties. The annual dues are five dollars. Three meetings are held each year—an annual meeting in January in Brooklyn, a meeting in early summer and another in the fall in the other counties. The summer and fall meetings are largely social, and are instrumental in promoting good fellowship among the physicians of Long Island. The winter meeting is scientific, and is followed by an evening supper.

*The Long Island Medical Journal*—Next to its meetings, the principal activity of the Associated Physicians is the publication of a monthly periodical—*The Long Island Medical Journal*—which goes to all the members. Each issue consists of forty pages, which record the activities of all the medical organizations on the Island. It has made a specialty of articles that present the fundamentals of the art and science of medicine from the standpoint of the general practitioner. The last issue, for example, contained a series of articles on tuberculosis from the standpoint of family doctors, and the preceding number recorded a series of papers on focal infection which had been read before the Second District Branch Medical Society. The Journal has also prepared and printed abstracts of papers which have been read before local medical societies, and which have had a strong appeal to the members.

The Journal has been the means of informing the physicians of Long Island regarding the major activities of the County Medical Societies, and especially of the work of the Committee on Graduate Medical Education of the Medical Society of the County of Kings. It has been a great factor in stimulating the activities of the local medical societies, and the interest of the members in the Medical Society of the State of New York.

The Journal makes regular exchanges with over 400 medical journals from all over the world, and is widely sought as representing the medical thought of a great medical center. The exchanges are given to the Library of the Medical Society of the County of Kings, where they are available to any physician who comes to consult them.

The Journal also conducts a book review department in which reviews are carefully prepared by the best critics on the Island. This department is carefully edited and the opinions of its readers are widely quoted by publishers. The books which are received for review are added to the Library of the Kings County Medical Society.

*In Conclusion*—Long Island is a section that is set off by natural boundaries. It contains about one-fifth of the population of New York State, and is largely self sufficient in a medical way. Its several sections include every phase of medical practice among every variety of people. Its medical organizations have evolved in a natural manner, and have been unified by an influential central organization. The outstanding features of its medicine are the development of an extensive system of graduate education of its physicians, and the practice of civic medicine by its medical societies.

# NEWS NOTES

## LIVINGSTON COUNTY MEDICAL SOCIETY

An editorial comment

It is not our intention to print any news of a controversial or derogatory nature in this Journal. The records of the meeting of the Livingston County Medical Society on March 24, which we printed on page 630 of last week's issue, indicated that the society was alive to its civic duties. The session lasted nearly six hours, and two excellent scientific papers were presented. Two important civic matters were discussed. While the Society seriously considered a suggestion of District State Health Officer Wakeman that the Society assume the direction of the official children's health clinics, the suggestion was not adopted, but the Society voted to request the State Department of Health to assist in instructing the public health nurses of the county in infant feeding methods. This was a commendable action by the society, and will doubtless lead to still greater activities in child welfare.

The second civic matter that was discussed was that of establishing and locating a county laboratory, which would receive State aid. The report which we printed indicated that the County Medical Society was taking a proper interest in the laboratory, and while the reso-

lution which the society passed was of the nature of a protest against the choice of the location of the laboratory, yet it seemed to us to be entirely proper that the report should be printed as the record of the action of the Livingston County Society. However, we are in receipt of a communication from Dr. Walter S. Goodale, Chairman of the Board of the Jackson Health Resort, Inc., to whom the contract for the laboratory was given in which he quoted evidence to show that the managers of the Health Resort had acted in good faith in offering a laboratory and diagnostic service which was convenient to the physicians of Livingston County and which conformed to the standards of the State Department of Health.

The report which we printed indicated that the protest was directed solely against the action of the Board of Supervisors, and not against any group of physicians. If we had any intimation that conditions were otherwise, we would have edited the report.

We feel certain that the physicians of Livingston County will settle their own problems in entire good nature.

F O

## NEW YORK STATE ASSOCIATION OF PUBLIC HEALTH LABORATORIES

Ninth Annual Meeting, Hotel Syracuse, Syracuse, May 12, 1925

Dr. Wilhelm Kolle, Professor of Medicine, University of Frankfurt-am-Main, and Director of the State Institute of Experimental Therapeutics, has accepted the invitation of the New York State Association of Public Health Laboratories to speak at its annual meeting at the Hotel Syracuse on Tuesday morning, May 12th.

Prof. Kolle's investigations in the field of chemotherapy opened up by Paul Ehrlich, have extended our knowledge of the therapeutic action of salvarsan and the newer arseno-benzol derivatives now used in the treatment of syphilis. He has also developed precise methods of testing the value of these drugs in the treatment of early syphilis and the limitations of chemotherapy in the later chronic forms of the infection.

Prof. Kolle's earlier work when a student and assistant of Koch, his researches in South Africa and the Sudan, and his collaboration with Wassermann in the "Handbook of pathogenic Microorganisms" are among his many distinguished contributions to medical science. He has just delivered the Herter lectures and the Harvey Society lecture in New York.

Among the papers to be presented at the Annual Meeting are "Report of a Case of Botulism" by Alvin G. Foord, Buffalo, "Development of a County Laboratory Under State Aid" by J. A. Dickson, Amsterdam, "Tropical Sprue," E. A. Baumgartner, Clifton Springs, "Bacteriophage," Stanhope Bayne-Jones, Rochester.

Members of the Medical Society of the State of New York are cordially invited to attend the meeting

Scientific Program, 9 30 A M.

Relative prevalence of types of pneumococci in sputa submitted to the Syracuse laboratory [5 minutes]

Henry N Jones City Laboratory, Syracuse.

A case of botulism Clinical and laboratory investigations [10 minutes]

Alvin G Foord and Anna G Forsyth (by invitation), Buffalo City Hospital Laboratory

An atypical Weil-Felix reaction its diagnostic significance, and the effect of inactivating the patient's serum [10 minutes]

Ruth Gilbert and M Coleman (by invitation), State Laboratory, Albany

Variations in the alkaline tide in urine and parallel variations in gastric acidity [10 minutes]

Roger S Hubbard, Clifton Springs Sanitarium Laboratory

Development of the Montgomery County laboratory with the Julius Wassermann memorial under state aid [10 minutes]

J A Dickson, Montgomery County Laboratory, Amsterdam

Tropical Sprue. [10 minutes]

E. A. Baumgartner and Glenn D Smith (by invitation), Clifton Springs Sanitarium Laboratory

Bacteriophage. [20 minutes]

Stanhope Bayne-Jones (by invitation), University of Rochester Medical School, Rochester

Address

Wilhelm Kolle, Professor of Medicine, University of Frankfurt-am-Main and Director of the State Institute of Experimental Therapeutics

---

### SCHOOL MEDICAL INSPECTORS

An informal dinner and round-table conference of the School Medical Inspectors' Association will be held at the Onondaga Hotel, Syracuse, May 13, 1925. Dinner will be served at 6 p m. Price, \$1.50. The conference will be held at 7 30 p m. Brief addresses will be given by Haven Emerson, M D, John E. Burke, M D, and Warren W. Cox, Ph D. No formal speeches

will be given. School medical inspectors are urged to be present to contribute to the success of the gathering. Come and let all present profit by your personal experiences. Send in a postal card that we may expect you.

WM A HOWE,

State Medical Inspector of Schools

---

### STATE COMMITTEE ON TUBERCULOSIS AND PUBLIC HEALTH

The annual meeting of the New York State Committee on Tuberculosis and Public Health of the State Charities Aid Association, will be held May 8, Hotel Biltmore, New York City.

---

## GORGAS MEMORIAL

"On January 1, 1925," states a recent report by Dr. Franklin Martin, Chairman of the Board of Directors of the Gorgas Memorial Institute of Tropical and Preventive Medicine, "the Gorgas 'personal health' educational campaign was inaugurated on a modest scale. Since then 10 newspaper articles have been released to 1,000 newspapers and press services, 25 radio talks have been broadcasted by State Committee members, and 75 medical journals and county medical society bulletins have published news releases and articles. 1,600 newspapers, many of them large metropolitan dailies, are now regularly printing Gorgas material, and radio stations at New York, Chicago, Memphis, Fort Worth, St. Louis, Louisville and San Francisco are broadcasting health talks.

"Last September the Republic of Panama authorized the issuance of a \$750,000 bond issue to finance the construction of the research institute. A campaign is now under way in Panama and the Canal Zone to raise \$10,000 for the Endowment Fund. In addition, \$10,000 worth of laboratory equipment is available for use when a sufficient sum is obtained to finance a research team.

"1,500 doctors, representing every branch of medicine, surgery and public health, in cooperation with prominent laymen and women, are now serving as State Committee members. In line with our belief that the Gorgas Memorial could be established without resorting to the usual campaign methods, this organization was carefully formed without elaborate publicity or undue expense. The Gorgas movement is now in a fair way to become the strong influence we hoped it would be when we began organizing our State Governing Committees a year and a half ago."

Speaking for the American Dental Association, which has lately added its support to the Gorgas Memorial, Dr. D. M. Gallie, remarks:

"General Gorgas was a sanitarian, a medical man and a great organizer. But most of all he was a man with a keen sense of proportion and an innate love of justice. This is best exemplified in the fact that he lent his cooperation to the legislative committee of the American Dental

Association in the successful effort to secure the passage of the equal recognition bill, in October, 1917.

"The program of the Gorgas Memorial Institute in which the dentists of the United States will cooperate calls for a nation wide campaign of education and instruction in the wisdom of an ounce of prevention. Thus will people be taught to consider the body as something to be kept constantly in condition, rather than something that must be repaired when it breaks down. This is a program which dentists can endorse, since we constantly urge our patients to come in for periodic examination of their teeth. Not only can we approve of the work of the Gorgas Memorial along these lines, but we can also give it our financial support.

"A plan for the participation of dentists with physicians and surgeons in the personal health campaign has been approved by the Executive Committee. It endorsed the suggestion that state committees be appointed and subdivided into county and city committees and that each committee and subcommittee be assigned a quota for the support of the Gorgas Memorial."

Before this column of Gorgas news items goes to press Gorgas Memorial members and those listeners-in on the radio who by now have learned to watch for "Gorgas talks" will have enjoyed the address of Dr. Foster Kennedy scheduled for 11:20 A. M., Wednesday, April 22nd, over station WEAJ, New York City. Dr. Kennedy's subject is Mental Hygiene.

The Gorgas Memorial plans an impressive radio program for Child Health Day, Friday, May 1st. Speakers and subjects have not yet been announced but it is rumored that Governor Alfred E. Smith will broadcast first, and be followed by several leading scientific medical members of the New York State Governing Committee. Most of the Gorgas better health talks are given over station WEAJ, New York City. Great credit belongs to the New York Health Speakers Bureau, New York City, Dr. Iago Gallston, Director, for invaluable assistance to the Gorgas radio program.

# THE DAILY PRESS

What happens to violators of the Sanitary Code in Greater New York? The question is answered by the *New York Telegram* of April 11th in a half column article which we are reproducing as a matter of interest to the 900 or more doctors who are health officers in New York State

In the year 1924 the Health Department prosecuted 22,481 cases in the criminal courts and \$103,217 in fines were assessed in the cases, according to a report made today to Health Commissioner Monaghan by James D. O'Sullivan, counsel for the department. The report indicates that there was a great variety of prosecutions for violations of the sanitary code

A lunch concern was fined \$500 for keeping for sale three barrels of clams which were not properly tagged, so that in the event that a person contracted typhoid from eating the clams the source could not be traced

A dairy concern was fined \$500 for selling adulterated milk. This milk was 35 per cent low in solids, and because of previous convictions of the company the heavy fine was imposed

A physician, prosecuted by the department, was sentenced to the penitentiary after his conviction for filing a false certificate of death. He claimed a patient had died from nephritis of the lungs, whereas, it was shown the actual cause of the death was determined by the medical examiner as septic abortion

"If the Health Department," says the report, 'had to depend entirely on the voluntary co-operation of the public in protecting the city against disease, without being able to enforce its orders, it is self-evident its activities would be curtailed to a great extent'

"The results obtained through the courts by enforcement of the various provisions of the sanitary code act as a deterrent against similar violations. These factors emphasize the importance of the results obtained through court decisions"

We have frequently commented on the reasons which popular articles assign to account for the spread of influenza. Last week we quoted a prominent health official who ascribes the spread to shaking hands. The *Bronx Home News*, March 29, quotes Surgeon General Cumming in ascribing influenza to the common drinking cup. The *Gloversville Herald*, April 10, dwells on the protective value of the 'resistance' of the body, and says

"Health officials have never yet succeeded in stopping an epidemic of influenza. The avoid-

ance of "flu" or its consequences is a personal problem for each individual

"This is the time of year to be particularly on guard against 'flu' and pneumonia—as the two always go together—for in most vicinities their ravages usually reach the maximum toward the close of winter

"Cleanliness, good physical condition and plenty of sleep are our best safeguards. Something besides germs is usually required to make us sick. Much depends on our general condition—our 'resistance'."

It is no wonder that the people are confused in considering the means of preventing the spread of influenza. There is a common reason why shaking hands and the use of a common drinking cup may spread influenza and other respiratory diseases, and that reason is the fundamental one of spreading the infectious excretions of the nose and throat. If the infectiousness of these excretions were emphasized, any one can apply the principle of shaking hands, the common drinking cup, and all other auxiliary means of spreading the disease

The *Syracuse Journal*, April 9th, carries a column article on the proposed annexation of the Village of Onondaga Valley to the city of Syracuse, and gives the protection of health as the principal reason for the annexation. The article says

"Spokesmen favoring annexation stressed the health conditions at the Valley and charged that they would react to the detriment of the city unless action is taken by acquisition to remove menacing conditions

"Dr. Sears cited figures showing that from the illness of one boy only a few months ago, 78 of 80 residents of Chaffee Avenue were stricken by illness, due to pollution of water supply. He compared conditions at the Valley today as similar to those in Syracuse 40 years ago, pointing out that with the guarded water system the city has reduced all contagious diseases, particularly typhoid and tuberculosis. He urged a water supply, sewers and creek improvement as three essentials in the event the Valley is annexed"

Reports of meetings of Boards of Health are often statistical and concern inconsequential conditions. The *Little Falls Times*, April 7th, contains an account of a meeting of the Board of Health in which business of real importance was transacted. A new milk ordinance was adopted according to the following account

"Health Officer Santry submitted to the board what was termed the model milk ordinance,

urged by the state department of health This was adopted, with the exception that the city will accept grade B pasteurized and grade B raw milk which otherwise meets the requirements Health Officer Santry stated the producers themselves were anxious to comply with the regulation, as it would enable them to get pay for the cattle that were found to be tubercular and that had to be slaughtered"

The Board considered a nuisance created by sewage in a dry millrace and settled it by asking the mill owners to flush the race periodically A committee was appointed to conduct a cleanup week The milk inspector, the health officer, and the public health nurse all made detailed reports The reports indicated that the work of the nurse far excelled that of the other two officials in its probable effects on health

The two Watertown newspapers, the *Times*, and the *Standard*, have printed a number of articles of interest to physicians The issues of March 26th contain plans for health promotion contests during a proposed health week

The issues of March 30th contain accounts of health talks given in eight Sunday schools by local workers in public health They also announce health talks in the Y M C A and the Y W C A

The issues of March 31st contain accounts of an address on periodic health examinations given by Dr H C Montgomery before the Zonta Club, in which he explained what constituted a real health examination and its value to the one examined

The issues of April 1st contain accounts of several addresses on health given before several civic bodies The value of serums and vaccines were emphasized by various speakers, and the story of dog-sled races to supply antitoxin to Nome was dramatically told Judging by the publicity reports Watertown put on an extremely practical program for health week

Glens Falls is in the midst of a scarlet fever epidemic, according to the *Post* of that city The March 28th issue of that paper contains an interview with Dr Selleck, the Health Officer, in which he is quoted as saying

"Two children who were suffering from the disease had not been treated by physicians until the disease had almost run its course Consequently many other children were exposed Five cases developed a month ago, but the cases were reported, the children were promptly quarantined, and the outbreak was checked Then came the startling discovery that other children, who were suffering from the disease had not been treated by physicians until after they had been in contact with hundreds of other children One of these children had been in school three days

while suffering from scarlet fever, another had attended a party"

Dr Selleck goes on to describe the beginning signs of the disease, and to warn the people of the precautions to be taken We believe that the health officer has taken the best possible course for the control of the disease, for the intelligent cooperation of the people is absolutely necessary

We commented on another outbreak of scarlet fever on page 351 of the February 27th issue of this JOURNAL, and quoted from a local paper an account of the adoption of the preventive measure of accounting for every school child every day How this has resulted is told in the *Palchogue Villager*, April 2, as follows

"On February 16th the system of accounting for every child every day was started and proved a great success in the grade schools In contrast, nine cases of scarlet fever were discovered among the pupils of the High School during February and March

"It is easy to account for every child every day in the grade schools where each pupil sits in one room under the eye of one teacher who can easily detect the first signs of illness But in the High School the students pass from room to room and no teacher sees a student long enough to determine its physical condition

"If the ill children were in the grades, they would be detected and sent home But their detection is almost impossible in the High School

"Who is responsible for the continuance of scarlet fever? Obviously the parents of the student, and the students themselves

"How long will the people continue to allow children to go to school with colds and sore throats when these signs may mean scarlet fever?"

The *Amsterdam Evening Recorder*, April 8th, contains a half-page verbatim report of an address on the fresh air class in the Amsterdam public school given by Dr E Harrison Ormsby, School Physician The doctor explained that the class was for undernourished children and that as a result of their low physical condition, they were also backward mentally He reviewed the results attained both physically and mentally, and ascribed the failure of a very few to gain to the great distance they had to walk to school

Dr Ormsby gave the following conclusions

"This fresh air class is one of the most important phases of school health work

"About two to four per cent of the school population come within the eligible class

"Children admitted gain in nutrition and weight, and the temperature shows a marked tendency to become normal

"The children keep up to standard grade

"Good hygiene is introduced into the homes"

Dr Ormsby's lecture is a valuable contribution to the literature on open-air schools

# BOOK REVIEWS

**RACE HYGIENE AND HEREDITY** By HERMANN W. SIEMENS, M.D. Translated and Edited by Lewellys F. Barker M.D. 12mo of 178 pages, illustrated. New York, D. Appleton and Company, 1924. Cloth, \$2.00

This octavo of 178 pages is a little gem in itself and has been translated by Dr. Barker in his usual facile style, without loss in the exact meaning of the text, which is a difficult feat.

A clearer, more concise statement of Weismann's "Germ Plasm" theory and Gregor Mendel's Law could not be found. The brief discussion of these in their relation to heredity in general and the heredity of acquired traits is straight to the point and throws a flood of light on the *status præsens* of the human race, as well as future possibilities for the hygienic improvement of individuals of the race, assuming the possibility of a practical application of these laws. Such studies are profoundly related to future political history.

As physicians, we are in duty bound to acquaint ourselves with the modern concepts of such race problems. It is a difficult task, involving intimate knowledge of intricate details of the biologic processes in cells, and while there is no short cut to such knowledge, a little book like this goes far on the road and is, therefore, not only fascinating but highly useful as a beginning.

We heartily recommend the book, as lucid in style and comprehensive in matter and a necessary addition to one's library.

J. M. VAN COTT

**THE PNEUMOCOCCUS AND PNEUMOCOCCAL AFFECTIONS** By L. COTONI C. TRUCHE and Mlle. A. RAPHAEL—English Edition by D. S. PAGE, M.A., M. B. CANTAB D.P.H., and E. A. MORTON, M.R.C.S., Eng., L.R.C.P. Lond. Octavo of 218 pages, illustrated. London: John Bale, Sons & Danielsson. 1924.

This book is an intensive study of the pneumococcus dealing in particular with its immunological reactions and leading up to the practical subject of therapy. The literature is quoted extensively and much original research is reported. From theoretical considerations based on animal experimentation the authors have evolved a polyvalent serum, which is advocated in the treatment of all forms of pneumococcus lobar pneumonia. The antigens are chosen with great care and different animals are immunized against these chosen strains the sera of the animals being pooled to form the polyvalent serum. The antigens represent strains of Types I, II and III (American classification) and Type IV (Borrel and Kerand).

This serum is highly effective with animals, but the clinical section of the book, which describes the use of the serum in practice is rather unsatisfactory from our standpoint because no mention is made of the type of infecting organism. The authors are content to diagnose pneumococcus pneumonia from a smear and not lose time by more elaborate study. They admit such study is of interest but fail to inform the reader whether such studies were actually carried out and if so what the results were. We believe that with the methods of Avery and of Oliver we have means of determining the type of infection in a period short enough to make it quite feasible to make the diagnosis before proceeding to treatment. We are quite willing to be convinced that a polyvalent serum is equally useful in all types, but the present study fails to present a very important link in the chain of testimony.

T. H.

**CHEMICAL DYNAMICS OF LIFE PHAENOMENA** By Prof. OTTO MEYERHOF. Octavo of 110 pages. Philadelphia and London, J. B. Lippincott Company, 1924. Cloth, \$3.00 (Monographs on Experimental Biology).

As the title implies, this volume is devoted to a consideration of the chemical basis and operation of certain 'vital' processes, viz., (1) Physico-chemical mechanism of cell respiration, (2) Autoxidations in the cell, (3) Chemical relations between respiration and fermentation, (4) The transformation of energy in muscle and (5) The energetics of cell processes. The respective chapters represent lectures delivered by the author to research workers here and abroad.

While not intended as an exhaustive treatment of the subjects selected, the volume sets forth rather clearly much of the fundamental and experimental data on which are based the existing chemical theories of the processes discussed.

FRANK E. MALLON

**FRACTURES AND DISLOCATIONS, IMMEDIATE MANAGEMENT, AFTER-CARE, AND CONVALESCENT TREATMENT WITH SPECIAL REFERENCE TO THE CONSERVATION AND RESTORATION OF FUNCTION** By PHILIP D. WILSON, A.B., M.D., F.A.C.S., and WILLIAM A. COCHRANE, M.B., Ch.B., F.R.C.S. Edin. 978 Illustrations. J. B. Lippincott Company, Philadelphia. 1925. Price \$10.00.

In general this book expresses the views of the Staff of the Fracture Service of the Massachusetts General Hospital. This service is in charge of Dr. Daniel F. Jones. The methods both old and new, which have given the most satisfying results, are presented. The Fracture Service, organized in 1920, has functioned with gratifying success under the guidance of able teachers.

This unusual opportunity has permitted the authors to give their profitable experiences. During the preparation of this work Dr. Cochrane has returned to Edinburgh. This new association has caused no radical revision in the book, but has served indeed, to amalgamate the opinions upon the two sides of the Atlantic.

The book is written for the general practitioner and stresses the mechanical methods of treatment rather than open operative surgery.

R. H. F.

**WHEELER'S HANDBOOK OF MEDICINE** Seventh Edition, edited by WILLIAM K. JACK. 12mo of 629 pages. New York: William Wood and Company, 1924. Flexible binding. \$4.00.

The seventh edition of this book includes the advances in medicine since the previous edition. There are 600 pages of accurate description and treatment of diseased conditions of the entire body presented in the most concise language possible. This Handbook of Medicine is more thorough and inclusive than many similar books and would be useful to one desiring such a short cut in reviewing. Seven editions prove the value of the book to many.

H. M. M.

**THE INSULIN TREATMENT OF DIABETES MELLITUS** By P. J. CAMMIDGE, M.D., D.P.H. Second Edition. 12mo of 216 pages. New York, William Wood and Company. 1924. Cloth. \$2.50.

In this edition following the first one of January, 1924 the subject matter has been brought up to date. A very good description is given of the experimental investigation leading to the discovery of insulin.

Considerable attention is paid, as is usual with the author, to causes of glycosuria other than pancreatic. The belief is expressed that it is important to look for associated disturbances in the digestive tract and that

short periods of fasting at the beginning of treatment are of value in combating these as well as giving rest to the pancreas

Where a hyperglycemia is associated with renal disturbance particular care is necessary in the use of insulin as even small doses are sometimes poorly borne, in the author's experience.

In general, the methods of study of the patient and rules for the employment of insulin are the same as are recommended in this country. The book is well written, by an authority on Diabetes. W E McCOLLUM

**THE TREATMENT OF FRACTURES IN GENERAL PRACTICE.** By C MAx PAGE, DSO, MS, FRCS, and W ROWLEY BRISTOW, MB, BS, FRCS. Octavo of 239 pages, illustrated. (Oxford Medical Publications.) London, Henry Frowde and Hodder & Stoughton, 1923. Cloth, \$4.00

This short treatise of 239 pages makes no pretense to be any more than a guide to the general practitioner in managing his fracture cases. A clear-cut, simple description of the important therapeutic indications is given and a method of treatment outlined whereby a good result may be obtained, little discussion of different methods of handling a given fracture is entered into. Some valuable advice is contained as to the prognosis of end-results and periods of disability for the various fractures. The influence of Sir Robert Jones on the minds of the authors is plainly seen, again and particularly in connection with fractures of the lower extremity the orthopedic viewpoint is emphasized and the use of walking calipers and braces discussed in greater detail than the general surgeon is wont to find in more complete treatises on this subject. Advances gained from war experience are adequately covered within the scope of the volume. Without question the book supplies a definite need and could be introduced with great profit into every hospital library as a guide to the resident staff in the management of fractures.

JAMES L COBB

**PRINCIPLES OF GENERAL PHYSIOLOGY** By SIR WILLIAM MADDOCK BAYLISS, M.A., SSc., FR.S., etc. Late Professor of General Physiology in University College, London. Fourth Edition, 261 Illustrations. Longmans, Green and Co., New York, 1924

In the preface to the first edition we find the following "An elementary knowledge of physics, chemistry, and biology must be assumed, unless the book is to become altogether unwieldy." Let it be understood that this same elementary knowledge old and lately required if the fourth edition (the edition under review) is to be read, understood and enjoyed.

The whole field of general physiology is covered and the various theories and works of men, other than the author and his assistants, are freely quoted. In fact the book constantly refers to the work of others and the photographs of eminent scientists are often reproduced and the particular work of these men reviewed in a short resume.

At the end of each chapter is found an admirable summary of the chapter, just read, in which controvertible matter as well as established questions are reduced to the simplest explanation and interpretation.

This is a book long to remain an authority, in its particular field of science.

G W P

**A TEXT-BOOK OF ANATOMY AND PHYSIOLOGY FOR SCHOOLS OF NURSING, NORMAL SCHOOLS AND COLLEGES,** by JESSE FEIRING WILLIAMS, MD. 12mo volume of 523 pages with 369 illustrations. Philadelphia and London W B Saunders Co., 1923. Cloth, \$3.00

This book designed for nursing schools, normal schools and colleges supplies rather too much than too little for easy assimilation by students of these schools.

There is much scientific substance and accurate fact

crowded between these covers. The sketches of embryology and histology are short and good. The osteology is concrete and sane for a book of this type. We suggest omitting the nerve supply in the description of muscles and using the space for a description of their action. The nervous system, circulatory system, respiratory system, excretory system, reproductive system, endocrine system and organs of special sense are well cared for anatomically and physiologically. The endocrine description is timely and of value to those for whom this very excellent little volume is designed.

T L V

**INTERNATIONAL CLINICS** Vols III and IV. By Leading Members of the Medical Profession Throughout the World. Thirty-fourth Series, 1924. Philadelphia, J B Lippincott Co., 1924

**Vol III** This is an excellent number of an always interesting periodical. There are five articles on Public Health and Hygiene, the subjects treated being Dental Hygiene, Malaria, Communicable Disease, Control of Health Examinations. Regarding the latter subject, Dr James J Walsh has much to say in their favor but also believes that harm is sometimes done to the patient who is susceptible to unfavorable suggestion. He thinks that some people are started on the road to various functional derangements but this is less likely to happen when the examination is made by the family physician instead of a stranger.

"Evolution in the Treatment of Syphilis" is a comprehensive review of the subject. Smithies presents his views in "A Clinical Consideration of the Management of Peptic Ulcer." He stresses the importance of a consideration of the varied etiology of ulcer, infectious causes taking first place, in his opinion. He thinks that the removal of a focus of infection will prevent recurrences of ulcers. His method of management is outlined.

Some of the other titles are, "Habit Spasm," "Variation of the Chloride Content of the Blood," a very good article by de Wesselow, "Bronchial Asthma" and some allied conditions, and "Observations on Celiac Disease" by C G Kerley.

In the "Outlook in Insulin Treatment," Hipwell and Gilchrist of Toronto give the histories of some of the early cases of Diabetes treated with Insulin in 1922. In following these cases to date, the authors conclude that in three which have been persistently maintained sugar free, the fact is illustrated that there is in such cases a regeneration of the Insulin production function. In contrast, two cases demonstrate another fact—that with the persistent excretion of small amounts of sugar, they require increasing doses of Insulin and do not show improvement in their carbohydrate tolerance. Another patient, of her own accord, took 95 units of Insulin daily for about 18 months without apparent ill effect.

**Vol IV** Some of the subjects treated in this number are Blastomycosis, Pellagra, Vincent's Angina, Bacillary Dysentery, Malaria and Intestinal Obstruction. Banting contributes an article on Insulin which elucidates the principles involved in a brief but satisfactory manner.

In discussing "The Effect of Tonsillectomy on Existing Visceral Disease," Hand ranks the naso-pharyngeal mucosa as next in importance to the teeth as an avenue of infection, then the mastoid cells and the tracheo-bronchial lining. He also thinks that the intestinal mucosa, the appendix and even the gall bladder "may open the door to organic heart or kidney disease." If one accepts the mucosa of various regions as a focus of infection he will feel helpless at times in his efforts at eradication.

Topics of interest to the surgeon are "The Use of X-ray and Radium," "Internal Fixation of Fractures," "Ethylene" and a Review of "Fractures of the Lumbar Spine."

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL 25, No 16

NEW YORK, N. Y

MAY, 1925

## A CONTRIBUTION TO THE ETIOLOGY OF THE CYSTIC OVARY

By G L ROHDENBURG, M.D., and A. M. HELLMAN, B.A., M.D.,

(From the laboratory of the Lenox Hill Hospital)

NEW YORK CITY

ANYONE having access to considerable material encounters cases in which the cardinal symptoms are apparently of ovarian origin. Operative interference in such instances frequently shows the ovaries to be slightly enlarged and more or less studded with small cysts. The etiology of this condition is, as yet, not definitely established, and the present paper is an attempt to add to the knowledge of the subject.

The present conception of the physiology of the menstrual cycle is that puberty having been established and a matured Graafian follicle having ruptured, a corpus luteum, which is chemically active for from ten to fourteen days, develops at the site of the ruptured follicle.

The histologic changes that occur in and about the ovum in the course of its development and recession are as follows. At birth, there are pres-

FIG. 2—Further stage of developing Graafian follicle, follicle cavity present.

FIG. 1—Primordial follicle with adjacent follicle in a later state of development, from six-months-old child.

ent in the ovarian stroma thousands of primordial follicles (Fig 1) and, under normal conditions, at least 250 of these go through the cycle of maturation, corpus luteum formation and subsequent absorption. All of the remaining ova sooner or later undergo a process termed atresia. These are physiologic facts that have been stressed by all who have considered the physiology of ovulation. They are perhaps too often forgotten by the clinician.

In the normal process of development, the cells about the ovum proliferate and differentiate into two zones, an inner zona granulosa, and an outer double layer called the theca. The continued proliferation of these cells increases the size of the follicle and forces it to the surface of the ovary, during which process a zona pellucida forms between the ovum and the zona granulosa, and a follicle cavity develops (Fig 2).

Subsequently, the rupture of the follicle occurs,

short periods of fasting at the beginning of treatment are of value in combating these as well as giving rest to the pancreas

Where a hyperglycemia is associated with renal disturbance particular care is necessary in the use of insulin as even small doses are sometimes poorly borne, in the author's experience.

In general, the methods of study of the patient and rules for the employment of insulin are the same as are recommended in this country. The book is well written, by an authority on Diabetes. W E McCOLLUM

## A CONTRIBUTION TO THE ETIOLOGY OF THE CYSTIC OVARY

By G L ROHDENBURG, M D, and A M HELLMAN, B A., M D,

(From the laboratory of the Lenox Hill Hospital)

NEW YORK CITY

ANYONE having access to considerable material encounters cases in which the cardinal symptoms are apparently of ovarian origin. Operative interference in such instances frequently shows the ovaries to be slightly enlarged and more or less studded with small cysts. The etiology of this condition is, as yet, not definitely established, and the present paper is an attempt to add to the knowledge of the subject.

The present conception of the physiology of the menstrual cycle is that puberty having been established and a matured Graafian follicle having ruptured, a corpus luteum, which is chemically active for from ten to fourteen days, develops at the site of the ruptured follicle.

The histologic changes that occur in and about the ovum in the course of its development and recession are as follows. At birth, there are pres-

FIG. 1—Primordial follicle with adjacent follicle in a later state of development, from six-months-old child.

FIG. 2—Further stage developing Graafian follicle, follicle cavity present.

ent in the ovarian stroma thousands of primordial follicles (Fig 1) and, under normal conditions, at least 250 of these go through the cycle of maturation, corpus luteum formation and subsequent absorption. All of the remaining ova sooner or later undergo a process termed atresia. These are physiologic facts that have been stressed by all who have considered the physiology of ovulation. They are perhaps too often forgotten by the clinician.

In the normal process of development, the cells about the ovum proliferate and differentiate into two zones, an inner zona granulosa, and an outer double layer called the theca. The continued proliferation of these cells increases the size of the follicle and forces it to the surface of the ovary, during which process a zona pellucida forms between the ovum and the zona granulosa, and a follicle cavity develops (Fig 2).

Subsequently, the rupture of the follicle occurs,

and at the site of the former follicle a corpus luteum develops through a collapse and folding of the follicle wall with changes in the structure of the thecal envelope. The thecal coats mingle their elements with the granulosa, and the granulosa cells enlarge and become converted into luteal cells. Fibroblasts and capillaries penetrate the theca and granulosa layers and finally fill the old follicle spaces, creating a solid spherical epitheloid structure (Fig 3). Recession of the corpus luteum takes place by contraction of the core, which may or may not become cystic or be the site of a hematoma. The lutein cells degenerate, the connective tissue becomes increasingly hyaline, the blood vessels show hyaline changes, and the corpus luteum, now called corpus albicans, assumes a smooth homogenous appearance, with a wavy outline and varied shape (Fig 4).

Another phase of the normal physiologic cycle for the ovum follows follicle atresia, which may occur at any stage before the rupture of the follicle, owing to either hydropic degeneration of the ovum or hemorrhage into the thecal layers (Fig 5 a, b). In the small follicles liquefaction of the ovum occurs, and a replacement fibrosis completes the process. In the larger follicles, cystic degeneration is followed by the absorption of fluid and the development between

FIG 3—Fully developed corpus luteum.

FIG. 4—Well organized corpus albicans. Patent condition of blood vessels may be noted.

the degenerating granulosa and thecal layers of a flat band of hyaline connective tissue which gradually increases in size. This band contracts, and through it, from the outer thecal cells, a

FIG 5—a Follicle in state of hydropic degeneration.

wavy connective tissue penetrates and fills up the cavity (Fig 6 a, b, c).

In origin, cyst formation in the ovary is, therefore, of one of two types—the corpus luteum and the simple follicle. Each is normal but becomes pathologic when organization fails to occur. In consequence of these cyclic changes, there are in any ovary, even before puberty, follicles in all stages of development and atresia.

In normal physiology, the cyclic changes just

FIG 5—b Follicle with hemorrhage in granulosa and thecal coats

FIG 6—b Intermediate stage of same showing hyaline zone.

described are accompanied by changes in other organs, one of which is the uterus. In this, the cycle as now generally accepted is divided into three periods. The intermenstrual period begins as soon as menstruation ceases, and ends with the onset of the premenstrual change, from four to six days before the onset of the bleeding. The endometrium at this period shows the glandular elements in the resting stage, with the glands straight and rather widely separated (Fig 7)

The gland lumina is devoid of secretion, and the stroma is composed of densely packed lymphoid cells. Since the presence of a corpus luteum has been repeatedly shown to inhibit menstruation, this phase of uterine activity is probably associated with the duration of the activity of the corpus luteum.

The premenstrual period (Fig 8), which follows, is characterized by a condition in which the glands become tortuous and show papillary in-

FIG. 6—a. Early stage of organizing atretic follicle.

FIG. 6—c. Terminal result of organization of healed cyst.

growths of the lining epithelium with distention of the gland lumina by the products of secretion. In the stroma, the closely packed cells become separated and the cell outlines become more visible. This phase is associated with recession of the corpus luteum and maturation of the follicle. In the third, or menstrual, period (Fig 9), the previous changes become still more marked and an edema of the stroma occurs with marked congestion of the capillaries and extravasation of red blood cells into the gland lumina and stroma. The glands discharge their secretions and the upper portions are desquamated, after which the endometrium returns rather rapidly to the condition present in the intermenstrual phase.

FIG 7—Resting stage of uterine mucosa.

Concomitant with the uterine and ovarian changes, there are symptomatic changes in the individual. A few days or hours before the onset of the flow, there is a sense of fulness in the lower abdomen, occasionally a backache, and in some instances marked tenderness of the breasts. In some females, thyroid overactivity occurs, with enlargement of the gland, while others have violent occipital headaches.

This rather sketchy review of the present conception of the normal physiology has been given so that the pathologic condition can be more properly understood.

About ten years ago, one of us was for a considerable time compelled to prepare sections of ovaries by the frozen section technic. These sections occasionally showed numerous corpora albicantes in which there were considerable amounts of luteal pigment still present. That such deposits had not previously been commented

FIG. 8—Premenstrual phase of uterine mucosa.

upon is probably due to the fact that in the paraffin method of preparation, practically all of this lipid goes into solution, and even with the frozen section technic, the pigment gradually loses its color, and in many sections is completely bleached in from six to eight weeks.<sup>1</sup>

In 165 specimens in which both ovaries were available for study, and in which there was no concomitant suppurative inflammation of the fallopian tubes, the ovaries were sectioned at right angles to the long axis, the cuts being approximately 3 mm apart. The surfaces of these sec-

FIG 9—Menstrual mucosa.

tions were examined for the golden-yellow pigment deposit which characterizes the luteal body. In twenty cases (12 per cent) no such deposits were found, in eighty-three cases (50

<sup>1</sup> The photomicrographs accompanying the present article were all made from frozen sections.

per cent), from one to three such deposits were demonstrable, in thirty-two (20 per cent), there were four deposits, in twelve (7 per cent), there were five, in eight (5 per cent), there were six, and in ten (6 per cent) there were seven distinct and separate areas of pigment deposit

Viewed from the statistical standpoint the amount of corpus luteum pigment present in this group varies from none to a large excess. It is justifiable to consider this pigment as the precipitated luteal secretion, in some of the ovaries there was an excess. If the average diameter of a fully developed corpus luteum is taken as 3 cm., it is estimated that in those cases having four or more pigment deposits the amount present varied from 1.25 to 3.75 times that present in a single corpus luteum.

Histologic examinations were made of 124 sets of ovaries. It appeared from this study that premature hyalinization of the vascular supply of the corpus luteum at times occurs (Fig 10), and when it occurs the corpus luteum recedes very slowly and does not undergo prompt hyalinization. The detritus of the luteal cells is not completely and promptly removed. Histologic examination also showed many microscopic areas of pigment deposit not recognizable in the gross (Fig 11). In ovaries in which there were more than four foci of pigment deposit, there were a large number of follicles in the process

Fig. 11—Persisting luteal pigment in corpus luteum completely hyalinized

Fig. 10—Premature sclerosis of blood vessel supplying corpus luteum, with resultant poor organization of corpus luteum.

of atresia and in the stage of liquefaction, with little or no attempt at healing in the manner already described. The cysts resulting from the atresic phenomena were usually numerous and of fairly uniform size, with occasional cysts of larger diameter. In such ovaries, the tunica

albuginea was markedly thickened, and occasionally infiltrated with lime salts (Fig 12).

The picture was different in ovaries in which there were no persisting pigment deposits. In these organs, small cysts were occasionally encountered, but they were not all in the same phase of atresia at the same time. Some were undergoing liquefaction, others organization, some were microscopic, others were larger. In

Fig. 12—Thickened ovarian capsule with lime salt deposits

brief, they presented a picture of the normal process of atresia. Thus, from the histologic examinations, it appears that the presence of small follicle cysts, up to from 3 to 4 cm in diameter, is pathologic only when the cysts show no tendency to undergo organization.

As might be expected from a knowledge of the physiology of the ovarian function, the symptomatology of the "cystic ovary" is variable, one or another group of symptoms dominating. In an analysis of fifty-five cases in which the ovaries were subsequently examined microscopically, the average age at which the condition drove the patient to seek surgical relief was 32 years, with the extremes at 21 and 49 years. Of the fifty-five cases, thirty-four were in women who had never been pregnant.

The average age at which the menstrual function commenced was 13 years, and in 90 per cent the menstrual period until the onset of the present trouble had been of the twenty-eight day type. In 10 per cent, the menstrual period had always been irregular. The duration of the flow averaged five days, with extremes of one and fourteen days. In 81 per cent of the cases, the chief complaint was pain in the lower abdomen more often on the right side. Irregular or profuse bleeding occurred in 47 per cent, amenorrhea of variable duration in 5 per cent. A mass was palpable in 32 per cent. In 15 per cent, uterine fibroids were found at operation, the average age in this group (with fibroids complicating) being 41 years. The duration of symptoms before surgical relief was sought varied from six months to five years, making the average age at onset about 28 years.

The symptoms may be considered under two heads, those having directly to do with the ovary, and those due to endocrine disturbances of either the ovary or one of the related ductless glands. The most common symptom referable to the ovary is that of pain, which occurs more often on the right side. The pain is characterized by local tenderness which is worse either about a week before menstruation (swelling of the ovary due to maturation of the ovum) or about a week thereafter (period of maximum size of the corpus luteum). This pain may for a period be localized in the ovary, but usually radiates to the lumbar region or down the inner aspect of the thigh to the knee. There may or may not be a palpable mass, depending often on the period of menstrual cycle at which the examination is made, the mass being present only when the Graafian follicle or corpus luteum is of maximum size.

The endocrine symptomatology may include all or only part of the picture given in the succeeding paragraphs. Thyroid function may be overactive, giving rise to considerable or slight emotional instability. There are often profuse sweats. At this period, there is an increase both in the

basal metabolism and the blood sugar. These symptoms are not permanent, but are usually present for a portion of each menstrual cycle.

In chronic cases, there may be evidence of thyroid exhaustion suggestive of mild myxedema, with a complaint of periods during which the hands or fingers feel boggy and stiff, with muscular pains associated with indefinite areas of muscular thickening or infiltration, and an increase of weight. Although patients of the latter type often complain of feeling puffy or bloated, physical examination does not confirm their statements. Occasionally the breasts become tender and lumpy before or during menstruation. This may at times be very marked.

Other endocrine symptoms are referable to disturbances of pituitary function. There may be violent headaches, usually occipital, with or without visual disturbances such as slight double vision or blurring. With these there is some increase in blood pressure and an increase of carbohydrate tolerance. The pituitary symptoms are also usually of evanescent character, lasting for only a part of the menstrual cycle. The direct ovarian endocrine symptoms are irregularities of the menstrual flow, either amenorrhea, metrorrhagia or menorrhagia.

A short series of cases which have been observed from four to ten years will be described in detail, in order to bring out the various symptom groups.

#### REPORT OF CASES

*Case 1 Simple type without endocrine disturbances*—An unmarried woman, aged 26, began to menstruate at the age of 13, and up to the onset of the present complaint the menses had always been regular, at twenty-eight day intervals and lasting from four to five days. Three years ago, the periods became irregular, appearing at increasingly longer intervals, up to three months. About this time, a pain appeared in the left lower quadrant, localized at first, but subsequently radiating to the lumbar region and inner aspect of the thigh. The pain was much worse before menstruation and was much relieved when the flow started.

Physical examination revealed an enlarged and very tender left ovary, and an enlarged but not tender right ovary. Tampons of glycerin and a sulphoichthyolate preparation, with dry heat applied to the lower abdomen, were resorted to, and in addition, 5 grains of entire ovarian substance was given twice daily. Heat treatment was continued for four months, when menstruation again became regular. Local treatment (tampons) was discontinued after five months, as the ovary ceased to be painful. Administration of ovarian substance in 5-grain doses every other day was continued for ten months. There has been no

return of symptoms after a lapse of five years, though both ovaries are still larger than normal

*Case 2 Thyroid overactivity*—An unmarried woman, aged 39, began to menstruate at the age of 15 years. The menses appeared every thirty days and lasted three days. At the age of 29, the patient first noticed localized pain in the right lower quadrant. This pain only rarely radiated down the leg to the inner aspect of the knee and was always much worse about ten days before menstruation. One year later, the opposite side was involved in similar fashion. A diagnosis of chronic appendicitis was made, and judging from the hospital records, an almost normal appendix was removed. There was no relief of symptoms.

The pain during the third year of the condition was made worse by bowel movements, and the patient preferred to remain constipated five or six days to reduce the pain which at times became so severe as to cause syncope. She also had backache. At the end of the third year, she developed an irregular fever of one to two degrees, which occurred intermittently. A diagnosis of pulmonary tuberculosis was made, and she underwent treatment in a sanatorium for one year, which did not influence the temperature in the slightest. The pulse then became increasingly more rapid, reaching 120 without exertion.

A diagnosis of incompetent ileocecal valve with prolapsed large intestine was next made, and a supporting plastic operation performed. The symptoms were not relieved. After a diagnosis of hysteria, she abandoned medical treatment of any kind for four years, when she presented herself with a continuance of the pain. She had lost 45 pounds (20.4 kg), the pulse averaged 115, the basal metabolism was +30, the blood sugar was 180 mgms per hundred cubic centimeters, and both ovaries were enlarged and very tender. There were no anomalies of menstruation. A double oophorectomy was performed, and two ovaries about half again the normal size and studded with follicle cysts were removed.

Recovery was uneventful, and three years after operation the basal metabolism was plus 5 per cent, the blood sugar, 125 mg. All of the previous symptoms had disappeared, the patient had gained 55 pounds (25 kg), and had almost none of the usual symptoms of a surgical menopause. Glandular therapy was not employed.

*Case 3 Thyroid hypofunction*—A married woman, aged 35, who began to menstruate at the age of 14 years, with thirty-day periods, lasting from three to four days, dated the onset of her present complaint as ten years previously. She had had two children, pregnancies and labors being uneventful. Her first complaint was a localized pain over the right ovary, the diagnosis being "diseased ovary." She refused operation. This pain persisted, and about two years later

the other ovarian region became painful, the pains radiating down the left thigh. About this time, there were periods of amenorrhea of two or three months' duration. This amenorrhea lasted about two years.

After the amenorrhea, her periods had returned to the thirty-day type, but the flow lasted a full week and was very profuse. For about three years before coming under observation, she experienced localized swellings, which commenced ten days before each period and lasted until the flow was almost over. These swellings would be present, at one time, in the neighborhood of the eyes or about the mouth, while, at another time, one or both extremities would be swollen or the fingers of one or both hands would be involved.

Physical examination showed both ovaries to be very tender and somewhat enlarged, but was otherwise negative. The patient was placed on entire ovarian gland, 3 grains, and thyroid gland one half grain, taken three times daily for a period of six months, and finally on one such dose every day for ten days before each menstrual period. At the same time, local treatment with tampons of glycerin and a sulphoichthyolate preparation was instituted, and was continued for three months, combined with applications of dry heat to the lower abdomen, which was continued for four months.

For the past four years she has been free of swellings and of ovarian pain. The menstrual periods are now of five days' duration, and the flow is less profuse.

*Case 4 Pituitary and thyroid dysfunction*—A woman, married, aged 39, mother of three children, began to menstruate at the age of 16 years, the menses being of the twenty-eight day type and lasting four days. The present trouble developed with an acute onset six years before. She was then pregnant five months with her third child, when she apparently became edematous, her blood pressure rose to 200 (systolic) and violent headaches in the region of the occiput occurred, with double vision. The urine was free of albumin. Blood chemistry examinations were not made.

A diagnosis of impending eclampsia was made, and from the sixth to the eighth month the patient was in a hospital to be ready for an emergency. Labor was induced at the eighth month, and was without noteworthy deviation from the normal. After confinement, the condition of the patient remained unchanged, and she gained weight rapidly, at one time weighing 70 pounds (31.8 kg) more than normal. When the child was 1 year old, the patient came under observation complaining of headache, double vision, increased blood pressure, general boggy-ness of the tissues, emotional instability and muscular pains, chiefly in the shoulder girdle and

trapezius. A routine urine examination, chemical examination of the blood, Mosenthal test diet and the phenosulphonephthalein test failed to demonstrate the slightest evidence of any kidney involvement. The basal metabolism was minus 30 per cent, the sugar tolerance test failed to show sugar in the urine after the ingestion of 550 gm of glucose, the blood pressure was 210, systolic. The general appearance suggested a moderate myxedema.

Physical examination failed to reveal enlarged ovaries or any tenderness in that region. About ten days before each menstrual period, there was an acute exacerbation of all symptoms, which lasted until the flow had ceased. The patient was placed on thyroid, 1 grain, and entire ovary, 5 grains, three times a day. Within one month, the blood pressure had fallen to 150 systolic, the headaches had disappeared, and the patient had lost 45 pounds (20.4 kg). Most of the muscular pains were gone and double vision no longer occurred. The same glandular combination was continued for the succeeding month, and pituitary gland, 2 grains, was added.

After one week of pituitary gland therapy, there was a prompt return of all the previous symptoms, without the swelling, and a return to a blood pressure of 200. Discontinuation of the pituitary substance was followed by a cessation of the symptoms. During the following year, five different attempts were made to give pituitary substance, and each was followed by a return of headaches, double vision and high blood pressure. In spite of the great improvement, there were recurrences of the complaint with each menstrual epoch, and for this reason, radiotherapy was given to cause temporary cessation of menstruation. The course of radiotherapy resulted in an amenorrhea of nine months' duration, during which there were no complaints.

Menstruation had been re-established for three months when the patient became pregnant, and with pregnancy came a sharp recurrence of all symptoms, which developed before we were aware that the patient was pregnant, although she insisted, as soon as the symptoms recurred, that pregnancy existed. A therapeutic abortion was performed, and the symptoms promptly abated. Massive doses of radiotherapy were then given, and permanent sterilization was accomplished. Endocrine therapy is still kept up, in much smaller dosage, thyroid, 1 grain, and whole ovary, 1 grain, being given once a day.

At present, her total loss of weight is 65 pounds (about 30 kg), blood pressure, 135 systolic. Double vision and headaches are but slight and occur at rare intervals. Menopausal symptoms of flushing and profuse sweats are markedly in evidence. Emotional instability is at times marked, at times, completely absent.

On the basis of the histologic studies described

in the previous paragraphs, an attempt was made to produce the condition of "cystic ovary" with the following hypothesis as a working basis. This condition follows incomplete recession and organization of the corpus luteum whereby an excess of luteal secretion is deposited in the ovary. This excess of secretion causes follicles that are developing to undergo cystic degeneration and inhibits in these degenerated follicles the normal progress of regressive changes.

Twenty-four female guinea-pigs weighing 300 gm were divided into two groups of twelve animals each. The animals were kept isolated from males, and had a common diet and similar surroundings.

The groups injected with a saline extract of corpus luteum received a total of seventy-five injections, while the other group received a total of sixty injections. The animals were killed after the injections were completed and sections were made of the thyroid, suprarenals, uterus and ovaries.

In none of the animals of either group were there any demonstrable changes in the thyroid, suprarenals or uterine mucosa.

The ovaries of the group injected with the saline product showed numerous follicle cysts which varied in diameter from 0.02 to 1.3 cm. These cysts had the same histologic characteristics as those observed in the human material examined. In some, there were areas of hemorrhage about the follicles, in others, this was not in evidence, simple liquefaction having taken place. In none of these cysts was there any evidence of attempted healing. In Figure 13, one ovary of each of the twelve animals is shown.

In the ovaries of the group injected with the "lipoidal product" no cysts were found, although atresia of the follicles was in evidence. In contrast to the previous group, the follicles were in varying stages of atresia, and there was marked evidence of repair in all its stages. One ovary of each of six animals of this group is also pictured in Figure 14, for purposes of comparison. It is interesting to note the differences in size of the ovaries in the two groups, the magnification being the same throughout.

On a basis of experimental results, it would appear that the mechanism of this process is probably as follows. Several corpora lutea fail to recede completely owing to premature hyalinization of the blood vessels supplying the gland. In consequence, there remains a deposit of luteal secretion, which slowly becomes an excess. This excess prevents normal healing processes in the degenerated follicles. The principle which inhibits is apparently present in a saline extract of the corpus luteum. It is not present in the lipoid preparation. The normal recessive phenomena which should occur in atresic follicles are in-

FIG 13—Low power view of guinea-pig ovaries after injections of saline extracts of corpus luteum

FIG. 13-a.

FIG. 14—Low power view of guinea-pig ovaries after injection of corpus luteum lipoid.

hibited, cysts of varying diameter develop, their size being dependent on the secretory activity of the epithelial lining

Excessive corpus luteum secretion is not responsible for remote or near endocrine phenomena. These endocrine phenomena, in the light of Loeb's communication, are probably due to the excessive amount of follicle fluid present in

the ovaries. It may be recalled that Loeb names two factors in the sexual cycle. The first factor is ovarian rather than associated with the corpus luteum. The walls of the maturing follicle secrete a substance that causes circulatory changes, growth processes, certain physical alterations and proliferation in the mammary glands, vagina and uterine walls, and, in a way, causes growth changes in the ovary itself, culminating in ovulation, which leads to corpus luteum formation.

The second factor in the sexual cycle is controlled by substances secreted by the corpus luteum. These secretions sensitize the uterus, make possible the formation of decidua or normal predecidual proliferation and facilitate the fixation and development of the fertilized ovum. They cause mammary growth and prevent proestrus, estrus, and ovulation, but not maturation of the follicles. There is an intermediate or a degenerative stage between the first and second factors.

The mechanism of the entire syndrome is possibly best explained as follows. The faulty recession of the corpora lutea being established, atresia of a number of follicles occurs and normal recession is interrupted. The follicles distend with secretion, and inflammatory changes having occurred in the capsule of the ovary, increased pressure is followed by pain. When for any reason the ovary becomes further distended, as with maturation of a follicle or development of

trapezius. A routine urine examination, chemical examination of the blood, Mosenthal test diet and the phenosulphonephthalein test failed to demonstrate the slightest evidence of any kidney involvement. The basal metabolism was minus 30 per cent, the sugar tolerance test failed to show sugar in the urine after the ingestion of 550 gm of glucose, the blood pressure was 210, systolic. The general appearance suggested a moderate myxedema.

Physical examination failed to reveal enlarged ovaries or any tenderness in that region. About ten days before each menstrual period, there was an acute exacerbation of all symptoms, which lasted until the flow had ceased. The patient was placed on thyroid, 1 grain, and entire ovary, 5 grains, three times a day. Within one month, the blood pressure had fallen to 150 systolic, the headaches had disappeared, and the patient had lost 45 pounds (20.4 kg). Most of the muscular pains were gone and double vision no longer occurred. The same glandular combination was continued for the succeeding month, and pituitary gland, 2 grains, was added.

After one week of pituitary gland therapy, there was a prompt return of all the previous symptoms, without the swelling, and a return to a blood pressure of 200. Discontinuation of the pituitary substance was followed by a cessation of the symptoms. During the following year, five different attempts were made to give pituitary substance, and each was followed by a return of headaches, double vision and high blood pressure. In spite of the great improvement, there were recurrences of the complaint with each menstrual epoch, and for this reason, radiotherapy was given to cause temporary cessation of menstruation. The course of radiotherapy resulted in an amenorrhea of nine months' duration, during which there were no complaints.

Menstruation had been re-established for three months when the patient became pregnant, and with pregnancy came a sharp recurrence of all symptoms, which developed before we were aware that the patient was pregnant, although she insisted, as soon as the symptoms recurred, that pregnancy existed. A therapeutic abortion was performed, and the symptoms promptly abated. Massive doses of radiotherapy were then given, and permanent sterilization was accomplished. Endocrine therapy is still kept up, in much smaller dosage, thyroid, 1 grain, and whole ovary, 1 grain, being given once a day.

At present, her total loss of weight is 65 pounds (about 30 kg), blood pressure, 135 systolic. Double vision and headaches are but slight and occur at rare intervals. Menopausal symptoms of flushing and profuse sweats are markedly in evidence. Emotional instability is at times marked, at times, completely absent.

On the basis of the histologic studies described

in the previous paragraphs, an attempt was made to produce the condition of "cystic ovary" with the following hypothesis as a working basis. This condition follows incomplete recession and organization of the corpus luteum whereby an excess of luteal secretion is deposited in the ovary. This excess of secretion causes follicles that are developing to undergo cystic degeneration and inhibits in these degenerated follicles the normal progress of regressive changes.

Twenty-four female guinea-pigs weighing 300 gm were divided into two groups of twelve animals each. The animals were kept isolated from males, and had a common diet and similar surroundings.

The groups injected with a saline extract of corpus luteum received a total of seventy-five injections, while the other group received a total of sixty injections. The animals were killed after the injections were completed and sections were made of the thyroid, suprarenals, uterus and ovaries.

In none of the animals of either group were there any demonstrable changes in the thyroid, suprarenals or uterine mucosa.

The ovaries of the group injected with the saline product showed numerous follicle cysts which varied in diameter from 0.02 to 1.3 cm. These cysts had the same histologic characteristics as those observed in the human material examined. In some, there were areas of hemorrhage about the follicles, in others, this was not in evidence, simple liquefaction having taken place. In none of these cysts was there any evidence of attempted healing. In Figure 13, one ovary of each of the twelve animals is shown.

In the ovaries of the group injected with the "lipoidal product" no cysts were found, although atresia of the follicles was in evidence. In contrast to the previous group, the follicles were in varying stages of atresia, and there was marked evidence of repair in all its stages. One ovary of each of six animals of this group is also pictured in Figure 14, for purposes of comparison. It is interesting to note the differences in size of the ovaries in the two groups, the magnification being the same throughout.

On a basis of experimental results, it would appear that the mechanism of this process is probably as follows. Several corpora lutea fail to recede completely owing to premature hyalinization of the blood vessels supplying the gland. In consequence, there remains a deposit of luteal secretion, which slowly becomes an excess. This excess prevents normal healing processes in the degenerated follicles. The principle which inhibits is apparently present in a saline extract of the corpus luteum. It is not present in the lipoid preparation. The normal recessive phenomena which should occur in atresic follicles are in-

severe epidemic once took place beginning in November

One would expect the extension of these epidemics to be general and regular, the contrary is true. An outbreak of poliomyelitis may spread to adjoining towns, or it may skip localities and appear in more distant communities. In 1910, a small epidemic occurred in Washington and shortly after in Philadelphia, but in Baltimore, which is between the two cities, there was a very slight increase in the number of cases. In 1907, when we had the severe epidemic in New York, a great many cases occurred in New England, whereas the country to the south and west of New York was comparatively free.

The most important aid in making the diagnosis of infantile paralysis is that obtained from an examination of the spinal fluid. In the instance which I related at the beginning of this paper, had the attending physician been careful enough to do a lumbar puncture, he would doubtless have reached the same conclusion as I did, and so have saved the patient from too early use of his leg, and the community from danger of contagion.

The spinal fluid in the beginning of poliomyelitis is clear, colorless and almost normal, there may be a slight increase in pressure. In a few days, however, there is a considerable change. The globulin reaction gradually increases and in the third week reaches its maximum. The most significant change, however, is in the number of cells. These rapidly increase, especially those of the mononuclear type. They may number hundreds, or even thousands. The normal count, as you know, does not exceed ten. The information given by an examination of the fluid, you will readily see, is considerable. I cannot, therefore, emphasize too strongly the importance and necessity of a lumbar puncture on all who develop an acute illness in the late summer or early fall. This is especially true if the illness appears to be one of slight importance, and occurs in a young person. These are the very types of cases which represent the mild non-paralytic or abortive form of infantile paralysis.

I think the most satisfactory classification made of this disease is that suggested by the department of health of this state. It is based wholly on the pathological anatomy. This classification has four types:

- 1 The non-paralytic or abortive type
- 2 The ataxic type
- 3 The cortical type
- 4 The ordinary spinal or sub-cortical type

The first the non-paralytic or abortive type, includes the very mild cases in which there is practically no paralysis or motor disturbances but in which there may be an involvement of the meninges.

In the second the ataxic type are included those cases in which the lesion involves the cere-

bellum, Clark's column, and the ganglia between the vertebrae.

The third, the cortical type, is that in which spastic paraplegia results. Thus third or cortical, and the second or ataxic types, are both rare.

The fourth, the ordinary spinal or sub-cortical, is the most common form. It is the one which is most frequent and the one which is self-evident. The lower motor neurone is affected and there results a flail extremity with subsequent atrophy and more or less paralysis.

After listening to this classification based on the pathological anatomy, you will realize that the disease is one which might be called multiple. The conception which you should form of infantile paralysis, is that of a general or systemic infection which has a predilection for attacking the nervous system. Therefore, both brain and cord are involved, and of course the symptoms must be both mental and physical. It is a disease, however, which may be so slight in its attack that the symptoms and danger signals may be mild enough in their manifestations to escape observation. This is especially true in the early stages, and in the mild, abortive types. This type is most baffling, and calls for the greatest care in diagnosis.

It should be borne in mind that there is one particular part of the nervous system especially prone to attack. The anterior horns bear the brunt of the illness. Now, just recall for a moment what would happen if the anterior horns of the spinal cord were affected, and you will readily grasp three or four leading symptoms of poliomyelitis. The anterior horns are the centers for controlling the motor functions. Therefore, there will be more or less paralysis. The anterior horns are the centers for the reflexes and form a part of the reflex arc. Therefore, there will be a loss of reflex. The anterior horns are the centers which nourish the muscles. Therefore, there will result atrophy of the muscles. Since the virus affects the posterior horns to so mild a degree as to be almost negligible, in this disease there will be no sensory disturbances. There will be no anesthesia, but on the other hand, inasmuch as the disease is a systemic infection, and therefore, must to a slight extent involve the entire nervous system, there will be an irritation of the posterior horns and the patient will complain of slight tingling and tenderness.

I said that there were other symptoms besides those of the spinal cord, and as one goes deeper into the subject, he realizes that the meninges, the coverings of the cord and the brain, and both the cerebrum and cerebellum may be affected. Therefore in some cases the physician will find rigidity of the neck, coma and Kernig's sign, if the cerebellum is affected, ataxia, if the cerebrum is affected, irritability, hyper-excitability, apprehensiveness, or stupor.

The meninges are almost always involved, a

another corpus luteum, the pain is increased. The simple excess of corpus luteum secretion would continue the resting stage of the menstrual cycle and produce amenorrhea, excess of follicular fluid would induce an undue continuance of the premenstrual phase with a resultant metorrhagia and menorrhagia.

In a similar manner, growth evidences in other organs, such as thyroid overactivity, and breast and pituitary changes are also attributable to excessive follicular fluid. The evidences of subgland function are explainable on the basis of fatigue following continued overstimulation from excessive follicular secretion.

Of the methods of treatment based upon such an hypothesis, the cases cited in other paragraphs are perhaps illustrative enough. Attempts

should be made to cause absorption of the follicle fluid by local treatment such as with sulphoichthyolate preparations and glycerin tampons, plus dry heat, combined with suitable endocrine therapy, such as thyroid medication for sub-thyroid symptoms, or suprarenal cortex for hyperthyroid symptoms. This proving futile, temporary or permanent cessation of ovulation should be attempted by radiotherapy, and this failing, a double oophorectomy should be performed.

It must be understood that just as the condition was a long period in arriving at its maximum, so treatment toward remedying the condition must be long continued, for it is well recognized in endocrinology that dysfunction of a gland is not quickly corrected.

## POLIOMYELITIS \*

By EDWARD LIVINGSTON HUNT, M.D.,

NEW YORK CITY

ON one of those cold and rainy days in early September, I met a friend who asked me how long it should take a patient to recover from an attack of intestinal neuritis. I replied that medically there was no such condition as intestinal neuritis, and inquired what were the patient's symptoms. He told me that just a week before his son, who was 19, had become suddenly ill with vomiting, diarrhea, and a temperature of 103, that the attack had been short, lasting three days, and that now a week later, the boy was able to be up and about, but complained of pain and tenderness in his right leg, and was quite lame. I suggested that the diagnosis was wrong, and that the patient had probably suffered a slight attack of infantile paralysis. I then asked if a lumbar puncture had been done. The reply was, "No, the attending physician did not think such a test necessary." Subsequent events proved that the case was one of infantile paralysis.

I tell you this for four reasons.

First, it describes very accurately the onset and early course of a typical case of infantile paralysis.

Second, it brings to your mind the fact that early in September a short acute illness in a boy of 19 should always suggest infantile paralysis, because the disease is most prevalent in the spring and fall.

Third, it emphasizes the importance of doing a lumbar puncture as part of a routine examination.

Fourth, it describes exactly the wrong treatment for the early stage of infantile paralysis.

The history and onset of this patient's illness had misled the doctor. This will remind you that in this disease the history is of minor importance. It is apt to be general, does not throw much light on the condition, and must not be given nearly so great weight as in other conditions. The story, which the patient afflicted with infantile paralysis, gives is typical of a systemic infection masquerading either as a gastrointestinal infection, or as a minor respiratory ailment. It may be so slight as to merit the name of ptomaine poisoning or grippe. It is the history of a few days indisposition, accompanied by a temperature of 102 or 103, and followed by an apparent complete recovery. So short is the attack and so marked the apparent initial recovery, that the whole illness encourages and misleads physician and patient, so that neither is on the alert for subsequent events. Even the slight tenderness which begins two or three days after is overlooked and given slight consideration.

Any acute illness, in a young person, occurring between June and November, ought to make the attending physician think of poliomyelitis, indeed it should impress itself on his mind so strongly that infantile paralysis ought to be considered until absolutely eliminated. Throughout the year occur sporadic cases, but the epidemics, with almost perfect unanimity, happen in the late summer and early fall. So unusual is it for an epidemic to appear at any other season, that the one or two which have occurred later in the year have been worthy of comment. In Norway, a very

\* Read at the annual meeting of the Fifth District Branch of the Medical Society of the State of New York at Oneida, October 2, 1924.

damage has been done, and also because we cannot forecast whether a severe attack is going to do much damage, or whether a mild one is going to do more. An attack, mild in its symptoms, may yet result in a slow but steady increase of paralysis lasting for several days.

The majority of these patients get well. I suppose it would be fair to take Lovett's figures, which are that 25 per cent completely recover. The prognosis is first as to life, and second as to the extent of paralysis. Unless the attack is exceptionally severe, which is evident at once, these patients live. The best that we can tell a patient is that there will be a recovery, that it will be more or less complete, and that it will begin when the tenderness subsides, but as to how far it will extend, time alone will show.

#### TREATMENT

The treatment should be divided into

- 1 The treatment of the acute stage,
- 2 The treatment of the convalescent stage, and
- 3 The treatment of the chronic stage.

I believe the most important treatment is that of the acute stage. The keynote of this treatment is rest and helping nature. It is far better to avoid drugs, and give the inflamed nerve cells an opportunity to get well. The extent of recovery depends upon two factors—the extent of the damage, and the care given in the acute stage.

Therefore, at once, as soon as the diagnosis has been made, the patient should be put to bed, fed nourishing food, and reassured with a cheerful environment. He should be made to take absolute and complete rest, in no way moving the paralyzed muscles. This treatment should continue for weeks until every evidence of the acute stage has subsided. The guide to this is the tenderness experienced by the patient when the affected muscles are touched. So long as this symptom is present, the patient is presumed to be in the acute stage of the disease, and, therefore, the only treatment indicated is one of rest. It is only when the tenderness subsides that one should consider at all the many aids which we have for treatment, such as massage, electricity and re-education.

Finally, when this tenderness has completely subsided, the patient passes into the second or convalescent stage. Positive harm can be done in this first stage by massage or by trying to stimulate the sick muscles. Before telling you what to do in the convalescent stage, I want to tell you a

few things not to do in the acute stage. I would not in that stage use any drugs. I would not apply any counter irritants to the spinal column, and I would not give any serum intravenously or intraspinally. Personally I do not believe you will do a great deal of damage by giving the serum, but I have yet to see very good results. Certainly there will be no very beneficial results, unless the serum is given in the very earliest possible days of the disease. Do not let a masseur or an electro-therapist have anything to do with the patient until all tenderness has subsided.

The treatment in the convalescent stage is one of stimulation and re-education of muscles.

When this convalescent stage has been reached one should try to ascertain just what muscles have been paralyzed and to what extent. Test all muscles, the test can be made in a hot bath, by means of both active and passive movements. Put the limb in such a position that weight and leverage cease to be factors.

Proceed then to use massage and to re-educate the muscles. Massage will improve nutrition, keep up muscular tone, and diminish atrophy. Do not give it to the point of fatigue else you will overture the muscle.

Re-education of the affected muscles will give most help. This treatment should consist of graduated muscle exercises given daily and arranged so as not to tire the muscles and also so as to bring into action the weak muscles as well as the strong. Too often the tendency is for the stronger muscle to derive all the benefit of the re-education exercises at the expense of the weaker.

Electricity is of some help, but is not nearly so important as muscle training.

Deformities must be corrected so that stretching of ligaments will be averted. If necessary keep the limb in its normal position.

The treatment of the chronic stage belongs to the orthopedist.

In conclusion then let me reiterate a few points.

- 1 Make the examination thorough, do a puncture.
- 2 Remember that tenderness is an important guide.
- 3 See that the patient has a long period of rest before beginning active treatment.
- 4 Muscle training is the greatest aid in treatment.
- 5 Muscle fatigue is the greatest danger.

stiff neck is a common and important symptom

The distribution of the paralysis should be mentioned. It is not peripheral but central, because of course it is not the nerve trunks which are involved, but the spinal cord segments, and for the same reason the paralysis is irregular in distribution, and incomplete as most muscles receive their innervation not from one particular segment alone, but from adjoining cord segments, that is, both from one segment and from the one partly above and the one partly below the affected one.

To sum up the symptoms, I want to ask you to think of four groups

- 1 An irregular, incomplete, and possibly unevenly distributed paralysis, or merely a loss of power affecting one or more extremities, especially the legs

- 2 An absence of anesthesia in the paralyzed limbs

- 3 A loss of reflexes in the paralyzed limbs

- 4 A definite change in the spinal fluid is shown by a great increase in the cells

In other words, in this disease you have three positive signs and one negative. The three positive are

- 1 Paralysis,

- 2 Destroyed reflexes, and

- 3 An inflammatory reaction in the spinal fluid

The negative sign is the complete absence of anesthesia. When these signs occur in an acute general systemic infection, especially prevalent in the late fall and in young people, the physician should think very seriously of poliomyelitis.

I do not wish to dismiss the subject of symptoms without saying a word about tenderness. For a great many years the significance of tenderness was disregarded, and I think even now is not made of sufficient importance. Tenderness means that when the paralyzed muscles are handled or very lightly squeezed, the patient suffers pain. This tenderness is of value in two respects: first as a symptom, and second, as a guide to treatment. There are very few conditions in which muscular tenderness occurs. Therefore its presence should greatly aid in the diagnosis. It may come early or late, but its presence is most significant.

The pathological changes which occur in this disease consist of congestion, which is accompanied by an exudate, hemorrhages, edema and anaemia, resulting from pressure upon certain vessels and finally a change in the nerve cells, which change is brought about by the toxic action of the virus. There are varying degrees, so that in some cases pathological changes are slight, in others moderate, and in the more severe cases, extensive. These changes occur throughout the nervous system. I mean by that, they are present in both the cord and in the brain. Those places in the cord which are most vascular are of course

the ones most likely to be affected, and therefore, it is in the cervical and lumbar regions that we most frequently find evidences of this disease, and particularly in the anterior part of the cord. Inasmuch as the disease is a general infection, other parts of the cord are also involved and small changes may be noted in the brain, pons, and medulla. Even in the posterior nerve roots changes will frequently be found. In the old cases, there is of course an atrophy of the cord, so that the ganglion cells degenerate, as do the fibres of the anterior horns and the nerve trunks. There is also an atrophy of the bones, so that the entire extremity—bone, nerve, and muscle is affected. The condition begins with a slight congestion, and if the attack is virulent, this is followed by an infiltration of small mononuclear cells. There is also infiltration of the cells along the nerve roots.

In addition to these changes in the nervous system, other organs are involved. The virus frequently affects the lymphoid tissues.

It is not possible to make any statement which is definite in regard to the virus of poliomyelitis. It is probably filtrable, gaining entrance through the mucus membrane of the naso-pharynx. The disease is probably contagious, certainly infectious, as washings from the naso-pharynx have communicated the infection to other patients.

#### DIFFERENTIAL DIAGNOSIS

There are many conditions from which we should differentiate infantile paralysis. I have seen cases of this disease diagnosed as rheumatism and meningitis. Other diseases which may confuse the picture are typhoid fever, cerebral hemorrhage, grippe, and mild respiratory or intestinal conditions.

In our large hospital services we have always found that the most difficult diagnosis to make was the differential one between anterior poliomyelitis and tubercular meningitis. In each there may be the fever, the rigidity, and the paralysis. In each there may be an involvement of cranial nerves, the Kernig sign and pain. In reaching a conclusion between these two conditions of tuberculous meningitis and poliomyelitis, the examination of the spinal fluid proves of most value and of great importance. In the meningeal condition, there is an increase of the sugar content, whereas, in poliomyelitis, this remains normal.

I now want to say a few words about the prognosis and treatment.

There is no disease in which the prognosis is more difficult than in poliomyelitis. The physician will be wise who after the first examination gives a guarded statement. This is largely due to the fact that we have very little data, very few and incomplete ways of judging as to what actual

is only necessary to be conservative in judging the number or the genuineness of such cases. The three additional influences which demand consideration in relation to the above generalization are heredity, modern living conditions, and the endocrine organs.

Heredity seems to be a real predisposing factor. As some families are full of diabetes, so others have nephritis, hypertension and apoplexy in generation after generation. The best explanation seems to be an inherited vulnerability of certain organs. Granting that practically everybody is sometimes subject to infections, there seems to be a special susceptibility to damage of the pancreas in diabetic families, and to damage of the cardio-renal-vascular system in other families. On the other hand, the great majority of cases of any of these diseases are probably not hereditary.

Present day civilization has been blamed for creating these medical problems which it faces. The chief evidence consists in the tremendous statistical increase of these diseases. Sedentary life, long hours, and psychic stress and strain are not known to cause either heart or kidney disease, though a popular idea makes them responsible for high blood pressure. On the other hand, others have pointed out that civilization in some respects has brought a quieter life. Primitive man, exposed to the constant terrors of wild beasts, human enemies, and his own superstitions, and likewise the medieval European, amid his numerous dangers of battle, murder, pestilence and sudden death, had in some respects more nerve-racking lives than ours. Laziness, obesity, and gluttony, including excessive protein diets, existed long ago. Alcoholism and other vices have on the whole diminished. Acute and chronic infections were much more prevalent formerly than now. If any metabolic diseases are more common among us than among primitive races, the difference may be due to something else than habits of life. Certainly the statistical increase among us as compared with our own ancestors for several generations or centuries seems to be explainable on the same two grounds for cardio-renal-vascular disease as for diabetes. First, we have better diagnoses and better statistics, so that the extent of the trouble is more accurately realized. Second, far more people live to middle and old age in other words, as the deaths in early life are prevented, more persons naturally become subject to the characteristic diseases of later life.

Endocrine disorders are a fad nowadays, and they are invoked by some writers to account for practically every obscure condition. Thus they are dragged into the question of hypertension, merely because the pathology is uncertain. But there is no evidence of adrenal excess as the basis of any typical case of hypertension. Thyroid excess

may presumably, like any intoxication, aggravate an existing tendency to hypertension, but its status is that of a complication, in typical hyperthyroidism there is no hypertension, and in typical hypertension there is no hyperthyroidism. The same is true of diabetes and hypertension; they may complicate and aggravate each other, but they are separate diseases, and observations of the frequency of hyperglycemia in hypertension cases and of hypertension in diabetic cases show merely the incidence of these complications. The sex glands have no scientific place in this subject. Castration in either sex does not raise blood pressure. Hypertension develops about the fifth decade of life as frequently in men as in women. A cure of hypertension by ovarian or any other kind of hormonal therapy has not been shown. The so-called hypertension of the menopause responds to diet treatment in the same way as other forms of hypertension. For these reasons the existence of any such separate entity as hypertension of the menopause must be denied.

#### PROPHYLAXIS

If we proceed on the hypothesis that all the cardio-renal-vascular disorders are the results of infectious or toxic damage of organs, we can face intelligently the second question, namely that of prevention. For this, two possibilities are open. The first and ideal one is to prevent infections. We are far from this goal, but yet acute infections are being either prevented or aborted by specific bacteriological methods with constantly increasing success. Thus, the recent discoveries in scarlet fever should aid in reducing the incidence of nephritis. Also, chronic and focal infections are being eradicated with increasing care and thoroughness. Therefore general hygiene, and the efficient application of medical and surgical knowledge as rapidly as it develops, offer real hopes for lowering the figure of the incidence of these diseases, which heretofore has risen so alarmingly.

The second possibility is to reduce the functional burden of organs that have been or may be damaged. Animal experiments in this Institute have proved that acute toxic injury of the kidneys is increased if they are at the same time subjected to a heavy load of nitrogen or salt excretion. An extreme application of this principle might consist in placing every scarlet fever patient on a diet low in salt and protein. Certainly in every form of severe acute infection tests should be made of the urine and if necessary, of the blood, and if the slightest renal damage is indicated the diet should be carefully restricted. Every acute nephritis, of whatever origin, should be followed by months of restricted diet, even if the renal trouble seems to have cleared up completely, and if the attack was severe, some degree of dietary restriction for the remainder of the

# HYPERTENSION AND THE TREATMENT OF NEPHRITIS\*

By FREDERICK M ALLEN, M D,

MORRISTOWN, N J

**T**HIS subject is obviously a large one. It covers a wide range of problems, largely unsolved, some of which must be mentioned very briefly and others omitted altogether. It should also be understood as standing second to no other subject in medicine in its importance for physicians and for the public.

The attack of medical science upon such a problem consists in learning the incidence, cause, prevention and most effective treatment. For clearness, we may best begin with some of the elements of present knowledge and methods.

## INCIDENCE

According to available statistics, cardio-renal-vascular disease stands first among the causes of death in adults. Cancer, tuberculosis and pneumonia rank below it. Within the past few years metabolic diseases in general have been winning their place as the leading division of medicine. Medical and popular attention has been drawn to the fact that there are a million cases of diabetes in this country. But the cases of high blood pressure alone possibly outnumber the diabetics, and when other types of renal-circulatory disease are included we may reasonably estimate the total number of sufferers somewhere between three and five millions. This has been the cause of death of the last two Presidents of the United States—Wilson and Harding—and also of Mrs. Harding. It is scarcely possible to pick up a copy of any large newspaper without seeing notices of deaths of more or less prominent persons from renal-vascular disease, and conspicuous among these are the sudden endings with apoplexy or heart failure resulting from high blood pressure. The problem is brought home to every individual, for in addition to the considerable chance of developing one of these disorders ourselves, there is almost a certainty that we cannot go through life without having some relative or close friend afflicted in this way.

## ETIOLOGY

The cause of cardio-renal-vascular disease is attributed essentially to infection. Infection in this sense means any acute or chronic disease in which bacteria or their toxins enter the blood. The proof is most complete for heart disease, in which it has been possible to demonstrate the bacteria in the heart valves. Embolic or suppurative nephritis, in which bacteria are demonstrable in the kidney, does not furnish adequate proof that other forms of nephritis are due to infection. But nobody doubts that tonsillitis, scarlet

fever and other acute fevers are frequently or occasionally attended by acute nephritis, or that such acute cases sometimes pass on into definite chronic nephritis. The connection of kidney disease with chronic focal infections in the teeth, sinuses or elsewhere is more difficult of precise proof but yet has been made so strongly probable by clinical observations that it is commonly accepted as established. The vascular diseases are the most recondite members of this group, and we are far from having either valid proof or general agreement concerning the etiology of arteriosclerosis or hypertension. But it will scarcely be disputed that hypertension is sometimes due to focal infection, as evidenced by the relief obtained by clearing up the focus. Also, elevation of blood pressure is not an uncommon accompaniment of the acute scarlatinal nephritis. Arteriosclerosis and hypertension may be caused by a chronic infection, such as syphilis. Furthermore, disorders of the heart, kidneys and blood vessels are so closely associated, and disease in one of these organs is so frequently complicated by disease in one or both of the others, that a common etiology is easily assumed. An assumption of this kind has actually become part of the generally accepted doctrine of nephritis. When hypertension occurs with acute scarlatinal nephritis, it is now generally interpreted as indicating toxic damage of the blood vessels, not of the kidneys alone. When edema occurs with either acute or chronic kidney disease, it is no longer explained as a simple retention of water or salt due to renal impermeability, but evidence has been found that altered permeability of the peripheral vessels is an important factor and apparently sometimes the sole factor. From all these considerations it is plausible to regard cardio-renal-vascular diseases as a common group, not only clinically but also etiologically, and to explain their cause and intimate connections as due to different infections and intoxications, which in different individuals produce various selective or generalized injuries of the heart valves or muscle, the kidneys, and the large or small blood vessels.

In this generalization, other poisons such as lead, mercury, alcohol and tobacco, and other influences such as exposure to cold, were ignored as being either debatable in status or of minor importance. No mention has been made of auto-intoxication, in the sense of absorption of harmful substances from the intestine. Here the point is merely one of proof. If it is proved that any substances, particularly products of putrefaction, are taken up from the bowel and cause any of these diseases, such cases are included under the head of infection or intoxication. It

\* Read before the Buffalo Academy of Medicine, March 11 1925

in research. Their practical status is open to question. In the first place, the average practitioner will not learn or perform them, and by making the subject appear unnecessarily formidable and complicated to him, they are detrimental to practical treatment. In the second place, why should the practitioner perform them? Granting that any or all of them turn out very badly, doubtless the prognosis is bad, but is there no simpler way of recognizing severe cases? In less severe cases, the practical reliability of the tests is not established. Furthermore, these tests pertain mostly to the function of nitrogen excretion. For salt and water excretion, the Ambard principle seems to lack practical value, and even the concentration and dilution test is not decisive. Any or all of these tests may show good functional capacity and yet the patient may die very soon of cerebral or pulmonary edema, apoplexy, heart failure, or secondary uremia. The argument is immediately made, these are circulatory accidents, while the tests measure only the function of the renal epithelium. The answer is, first, is it certain that a test can distinguish infallibly between epithelial and circulatory disturbances? and second, is the physician interested in a theoretical question of this kind, or in the practical questions of how to treat his patient and whether the patient is likely to live or die?

**Diet tests.** A simple classification was suggested above for its practical usefulness, and now an equally simple basis will be proposed for judging the severity, treatment and prognosis. If a case is to be treated at all, a diet is necessary, and this can serve as the most practical function test. Our cases in the Institute are studied by the usual methods for the usual theoretical purposes, but it seems reasonable to base a practical estimate of a renal-vascular disorder upon observations of what the renal-vascular system is able to do.

First, if a patient is able to eat a high protein diet without abnormal increase of non-protein nitrogen (or urea, whichever is preferred) in the blood, his nitrogen excretion is satisfactory and protein need not be restricted, unless as a theoretical precautionary measure. If moderate or severe protein restriction is necessary to reduce the blood nitrogen to normal, the nitrogen excretion is moderately or severely impaired. If limitation to twenty or thirty grams of protein, or a temporary protein-free diet, fails to bring the blood nitrogen near to normal, the nitrogen function is dangerously impaired, and, though discrepancies exist, the danger of uremia bears a crude relation to the height of the blood nitrogen.

Second, if a patient is able to eat unlimited salt without edema or hypertension, his salt function is adequate and prohibition of salt is unnecessary, unless as a theoretical precaution. If moderate or severe salt restriction is necessary to clear up edema or hypertension, the salt function is re-

garded as moderately or severely impaired. If the strictest salt exclusion fails to clear up edema or hypertension, the case is considered dangerous in proportion to the severity of the persisting symptoms. There are exceptions to all rules, but in general if any large dropsy, or blood pressure much above 200 mm, continues in spite of rigid exclusion of salt, not many months of life are to be expected.

I shall not attempt to mention the incidental or emergency therapeutic measures with which every physician is familiar, but some reference may be desirable to certain proposals which have attracted more or less recent attention. The theory of acidosis as the governing factor in either nephritis or edema, and the clinical use of Martin Fischer's alkaline injections, seem to have no sound support. Sansum makes the more rational suggestion that the diet should be so chosen as to furnish a nearly neutral urine, on the ground that a strongly acid reaction is injurious to the kidney. If acid retention has occurred, as indicated by high phosphate and low bicarbonate figures in the blood plasma, alkali may be administered not merely as sodium bicarbonate, but perhaps preferably by magnesia or calcium salts, which can be excreted through the bowel. Several suggestions have been made for the severe edema cases which are not cleared up by salt restriction. Where there is no important nitrogen retention, a few authors both in Europe and America have recommended high protein diets. I have not tried the plan in enough cases to contradict these claims, but can only say that in the few cases in which I have tried it the results were bad. Likewise with the recommendations of calcium chloride for edema, others have reported benefit, but my personal experience has been small and unsuccessful. Also I do not believe in the scientific soundness of the recent tendency to hold sodium responsible for all the trouble and represent chlorine as harmless. The well-known diuretics, especially of the caffeine-theobromin group, undoubtedly drive out some water which salt-free diet fails to remove, and still greater claims are made for some new drugs. The most prominent of these is novasurol, a mercurial which has been described as acting miraculously in many cases both of edema and of ascites, though in some other cases it has been found to produce disturbances such as bloody diarrhea. I have not tried it, for lack of suitable cases. In fact we have more important theoretical investigations which we are prevented from carrying out by lack of severe edema cases, and we should be thankful to anybody who would send us cases of marked edema, either nephritic or cardiac, on a charity or any other basis. Actually, edema cases which are resistant to strict salt-free diet are comparatively scarce. Those which resist lax salt restriction may still retain enough

patient's life is a measure of prudence. Such diets need not be particularly irksome, and by their use there is a chance that in some cases the danger of acute nephritis may be avoided, and that in other cases the onset of chronic kidney disease months or years after an acute nephritis may be prevented.

It is a doubtful question whether the eating habits of the general population need any change on account of these diseases. We have confirmed Newburgh's observation that excessive protein ingestion may produce signs of renal irritation in healthy persons, but it appears improbable that the meat or protein content of the average normal diet is a cause of kidney disease. There is ground for criticism that food is salted too heavily in many restaurants and also in many homes, but there is an apparent tendency to reduce the unnecessary use of salt, and it seems reasonable to believe that the moderate use of salt in general is not harmful and may be beneficial. On general principles, excesses in alcohol or tobacco must be considered harmful, though their direct connection with renal-vascular disease is uncertain.

#### TREATMENT

The third question, that of treatment, is necessarily the chief one to occupy the attention of physicians. Vital organs having been damaged, the essential treatment is to relieve them from functional overstrain. Here a division must be made, at least theoretically, between cardiac cases, which are treated on mechanical principles by muscular rest and stimulation by drugs, and renal-vascular cases, which are treated on chemical principles by diet.

In a brief summary of this kind, scarcely any mention can be made of anything except this all-important diet therapy. Sweating and purging may have a slight temporary usefulness in acute cases or in acute emergencies of chronic cases, but they are not equal in importance to one gram of salt or nitrogen in the daily diet. There is sometimes room for a skillful use of drugs, but the best principle is to refrain from putting into the body anything that the kidneys have difficulty in excreting, rather than to try to force a greater excretion. It must be understood that diet and excretion do not pertain to the kidneys alone. The elimination or retention of the substances in question involves the heart and the entire vascular system, and also all the tissues of the body. This fact is the basis of the general diet treatment of cardio-renal-vascular disease.

**Classification.** Obviously, it is necessary to break up this generalization into the different special diets suited to the different forms of disease. Many classifications of these disorders have been attempted, and we now follow the classification of Volhard as the latest and best. But

agreement between authorities is by no means reached yet, and for physicians at large clearness is more important than complicated or disputed pathological details. It is possible for practical purposes to ignore the morphologic pathology, which is the field of chief difficulty and disagreement. The chemical viewpoint is the simple one, the therapeutic viewpoint is the indispensable one, and these two happen to be identical. I believe the general practitioner will be aided by considering renal-vascular disease as divided on this basis into three type forms.

First, there is a form characterized essentially by nitrogen retention. Among morphologists, these cases are regarded as true nephritis, in the sense of an inflammatory etiology. Also the term glomerulonephritis has been applied by those who hold the glomerular changes as the decisive feature. But the anatomical subdivisions need not be mentioned here, because on the whole it is not feasible to differentiate them clinically. The important clinical fact is that this form tends to end in true uremia.

A second form is characterized preeminently by edema. Heavy albuminuria and anemia are also typically present, but not hypertension or nitrogen retention. Death may occur from the fluid accumulation or from circulatory or general weakness. The term nephrosis has become familiar for such cases.

The third form is characterized essentially by high blood pressure, and it tends toward death by apoplexy, heart failure, or pseudo-uremia. It is better that the term eclampsia should not be limited to puerperal cases but should be extended to all cases of false uremia, in which death often occurs with convulsions.

It must also be understood that all possible gradations and combinations occur between these three forms, and that the majority of cases are mixed rather than pure. Furthermore, secondary changes may become superimposed upon the primary ones, so that cases may appear to alter their clinical character. These facts furnish a defense against the criticism that this classification disregards fundamental pathological differences. Such differences, even if distinguishable by tests, do not affect treatment in the slightest and therefore have no particular value for the practitioner.

**Renal function tests.** This brings up the question of renal function tests and their usefulness. The excretion of test substances, notably the dye pnenolsulphonephthalein, the mathematical calculations of Ambard and his imitators, the retention of special substances such as creatinine or indican, trials of the concentrating and diluting power of the kidney, ordinarily performed by Volhard's plan in Europe or the Mosenthal modification in America, these and many other tests furnish theoretical information and have a place

plicated with diabetes are still among the most favorable prognostically, provided the diabetes is efficiently treated, and cases complicated with nephritis are still the worst in all respects and furnish the highest proportion of deaths. Otherwise, we lack prognostic indications, neither the height of the blood pressure nor anything else in the examination gives advance notice whether the condition can be controlled successfully or not.

The experience regarding complications remains as before. Apoplexy becomes rare when the blood pressure is reduced, and this rule holds even for patients who have previously had one or more strokes. On the other hand apoplexy keeps its usual frequency in cases where the pressure is not reduced. Myocarditis, heart failure and all cardiac complications are benefited as a rule, and sometimes very strikingly, by reduction of the pressure, but digitalis and the usual cardiac treatment may still be needed. The existence of nephritis with high blood nitrogen may sometimes call for a low protein diet prior to the withdrawal of salt, to avoid possible danger of uremia. But we have never seen a case in which salt exclusion was contra-indicated, and sometimes the renal function improves and albuminuria diminishes or disappears, presumably because of better circulation through the kidney. Retinitis is a grave, but by no means necessarily fatal sign. As a rule it can be permanently arrested when the blood pressure is controlled, and the prevention of blindness is in itself important enough to justify the whole treatment. Renal or cardiac "asthma" is generally relieved quickly and completely. The results with true angina pectoris are among the poorest, relief, if obtained, is apt to be transitory or partial, nevertheless the diet plan is probably better and safer than the spectacular surgical procedure of section of the sympathetic. Other vascular complications such as the so-called "crises," and also the flushings and other symptoms associated with the menopause, generally pass off gradually, if the pressure is controlled.

The results in severe cases furnish the most severe test of a treatment, but they cannot be the best results. The latter can be obtained only by treatment at the earliest and mildest stage possible. At such a stage, when the elevation of pressure is slight or brief, when symptoms are slight or absent, and when a little rest and vacation suffice to clear up everything, the condition should not be ignored, and neither should the prescription be rest, relaxation, or climate. A busy life does not cause hypertension, and rest does not reach the underlying cause or halt the progressiveness. The treatment should be by careful diet from the beginning, and by this means there is good hope of warding off the severe stage and most of the complications. The patient should be allowed to work, and invalidism should

not be fostered unless in the most severe type or stage of the disease.

#### OTHER USES OF SALT-FREE DIET

It may be remembered that in subdividing cardio-renal-vascular disease at the beginning, we split off the cardiac cases from the renal-vascular cases, on the ground that the former are treated mechanically and the latter chemically. A reunion is possible at this point, by calling attention to the benefit of diet in heart disease. It is unfortunate that books on the heart are so deficient on the subject of diet, and that most physicians who see a decompensated heart case think only of rest and digitalis. Whenever there is a tendency to edema, salt restriction is valuable for diminishing this tendency, easing the circulation, and reducing the need of driving the heart with drugs. Dry diet should not be ordered without excluding the salt which creates thirst.

It is doubtful if diabetes insipidus belongs anywhere in the cardio-renal-vascular group, but a salt-free low-protein diet is the best practical means for diminishing the thirst and polyuria.

Enuresis in children is occasionally a symptom of diabetes or kidney disease, but is generally a harmless condition which becomes very annoying when continued to too great an age. Abundant urine is generally one factor, and a cure is often possible by the use of salt-free diet and corresponding restriction of fluids until the habit is broken.

There are numerous other ways in which an understanding of the principles of metabolism and diet will be found useful in general medicine.

#### PRACTICAL APPLICATION OF TREATMENT

Summarizing broadly and briefly, the physician treating renal-vascular disease has to combat three things, namely nitrogen retention, edema, and hypertension, and for this purpose he has two weapons, namely low protein diet and low salt diet. These stipulations are perfectly simple to understand and to fulfill, but for successful treatment we must insist relentlessly on the equally simple fact that *they must be understood and must be fulfilled*.

Protein restriction is easy. Any physician who can prescribe a diet at all can easily make up three standard menus, one of them containing perhaps 30 grams of protein, another perhaps 60 grams, and another 80 to 100 grams. These may be used in testing the patient's power of disposing of nitrogen, and for the later treatment with low, moderate or high protein diet.

A salt-free diet will appear a childishly simple matter to the average physician, until he encounters the difficulty of making it accurate and appetizing. He should take notice of the fact that most specialists or others who have obtained no benefits from salt-free diets for hypertension have

functional capacity that they can respond to the above artificial forms of stimulation. But it is better to avoid all possible dietary strain upon a damaged function than to attempt to stimulate that function to overwork, and when the salt eliminating function is so feeble that edema persists in spite of rigid salt exclusion, I doubt if any of these artificial measures will give much benefit for any very long time.

**Results.** Turning to the results of diet treatment, we must recognize that they make up a brilliant chapter in modern medicine. Both the severity and the progressiveness of kidney disease have been reduced by dietary control. To a very large extent, uremia is prevented or greatly postponed by the protein restriction in general use. Thanks to salt restriction, as already mentioned, dropsy has become comparatively rare and seldom reaches the huge proportions which were previously common. Other kinds of therapeutic achievement—a surgical operation, or a new serum for an infectious disease—are more spectacular and impress the public accordingly, but the medical profession are agreed concerning the beneficent results of these diet methods.

There is no such unanimity concerning salt restriction in hypertension. We have revised the forgotten or ignored French work on this subject and have attempted to place it on a more accurate and efficient basis. Our observations, that salt restriction when accurately carried out gives strikingly beneficial results in the great majority of hypertension cases, have been confirmed by some writers but contradicted by others who have great experience and reputation. On this point, therefore, I am simply in the position of reaffirming my previous statements, and continuing to reaffirm them until they receive the acceptance which facts must ultimately win.

The benefits of salt restriction for hypertension are demonstrated partly by the immediate results. In many cases there is a transformation within the first few days or weeks, which is not explainable by rest, psychic influence, accident, or any other hypotheses. A stronger demonstration is afforded by the permanent results. Our previous publication<sup>1</sup> comprised an experience of four years and 180 cases, mostly severe. The pressure was reduced to normal in only a small minority (34 cases, or 19%). In 75 other cases (42%) the relief of pressure and symptoms was sufficient that the patients became subjectively well and remained so. In other words a total of sixty per cent of the cases gave striking success. In 16 other cases (9%) there was partial or transitory benefit. In 55 cases (30%) complete failure was acknowledged because there was no perceptible improvement beyond what might be attributed to rest and other routine measures.

The total mortality for the four years was 25 (13.8%).

We are now able to extend this experience to six years, and enlarge it with 148 cases in which the blood pressure was regularly above 190 and generally well above 200 mm. The percentages of success and failure have remained practically the same. We previously pointed out that these percentages are practically independent of time. If the pressure and symptoms are relieved, this relief is obtained rather quickly and generally continues indefinitely. In other words, the progressiveness of hypertension, which is the worst element in the prognosis, is arrested in the successful cases. On the other hand the unsuccessful cases are refractory from the beginning. There are exceptional cases, which begin successfully but end in death or relapse, or which on the other hand are refractory at first, but yield to months of continued rigid diet, but these are few. In line with these statements is the fact that our total mortality for the six years is 43, or 13.1% of the 328 cases.

These figures must be interpreted in the light of statements by other authors, that the majority of patients with severe hypertension are dead within five years (Janeway), and the majority of those with diastolic pressure above 120 mm are dead within two years. Our cases are unselected, we have been in the position of inviting physicians to send us their most hopeless cases, and in general they have done so. The tables in our previous paper showed that the diastolic as well as the systolic pressures have been high. In addition, all kinds of complications with the uremic form of nephritis, pre-existing apoplexy, heart disease, diabetes, and also old age are included in the series. One dealing with the patients does not receive the impression of thirty per cent of failures. Admitting the record of approximately 110 failures among 328 cases, based on the objective fact that there was no important reduction of blood pressure, the total of 43 deaths in six years would not make a very bad percentage if based on the failures alone, without regard to the rest of the series. Our actual belief is that the salt-free diet is beneficial in practically all cases, and that it has at least mitigated symptoms and prolonged life even in the majority of the cases classed as failures.

We divided the pure or essential hypertension cases into two classes, a majority with plasma chloride concentrations above 580 mg per 100 cc, and a minority with concentrations below 580 mg per 100 cc. Though the method for plasma chloride analyses is not as exact as desirable, high initial figures for chlorides in both plasma and urine may still be regarded as a favorable sign. This is rational, because if the body does not contain much chloride there is less chance of change by the exclusion of chloride. Cases com-

## THE FALLACIES OF A NEGATIVE PREOPERATIVE URINE REPORT

By HOMER L. NELMS, M.D.,

ALBANY, N. Y.

THE majority of surgeons require a preliminary routine urine examination on every patient before a general anesthetic is given. The object of this is to determine whether they are dealing with a nephritic or a diabetic condition, either of which, if present materially influences the prognosis in the case.

In many clinics this examination is made on the A. M. voiding. There are perhaps several reasons why early morning voidings are usually selected. In the first place, many patients requiring what are called selective or interval operations do not come into the hospital until the evening before operation, and in these cases the A. M. voidings represent the most convenient specimen that can be obtained. Secondly, the A. M. specimens are sent to the laboratory and examined within a few hours after voiding, and many surgeons place a great deal of emphasis on this early examination. In the third place, it is thought that the early morning voiding represents the functional activity of the kidney during the night and hence is a more representative specimen than a single daily voiding.

Having satisfied himself that the patient has an operative condition, the surgeon has the urine examined, and if it contains sugar albumen or casts he immediately begins to consider the advisability of more extended observation. Suppose, however, as is most often the case, the preoperative urine report is negative, what then? The surgeon proceeds with the operation without fear. It is for the purpose of emphasizing the fallacies of a negative preoperative urine report that this paper is written.

## A NEGATIVE URINE DOES NOT RULE OUT THE PRESENCE OF DIABETES

It has been estimated that we have in this country about two million diabetics, either potential or real. Assuming that the total population is 120 million we might say that one person in sixty has diabetes in some form. It is true that many cases are mild, and perhaps these figures have been overestimated, but this is a sufficiently high percentage to make diabetes a frequent complication in surgical conditions, and the careful surgeon must be on the lookout for it.

The advent of insulin has stimulated our interest in blood chemistry, so that it is safe to say we are making ten times as many blood sugar determinations today as we did three years ago. In comparing the relative sugar content of the blood with that of the urine it has been found possible to have a negative urine with a high blood sugar. That is, there exists what has been called a high renal permeability. In other words, there is a certain group of cases in which sugar

does not appear in the urine until the blood sugar has reached a high concentration. Dr. Henry John of Cleveland, in a series of 714 observations, found that 18 per cent of cases in his series had negative urines with blood sugar concentrations high enough to classify them as diabetics, some of them severe. The blood sugar level at which sugar appears in the urine varies with the individual and it is manifestly impossible to tell to what height the blood sugar may go before glycosuria develops. Were it advisable to follow cases over a period of years with frequent blood sugar and urine examinations, some interesting data on this point might be obtained.

It is common knowledge that in diabetics under treatment with diet and insulin, the glycosuria disappears long before the blood sugar has reached a normal concentration, the accompanying table illustrates this point very well.

TABLE SHOWING VARIOUS BLOOD SUGAR CONCENTRATIONS WITH NEGATIVE URINE

Case No.	Fasting Blood Sugar Mg Per 100 c. c.	No. of Subsequent Blood Sugar Determinations.
1	405	10
2	327	5
3	285	15
4	275	8
5	273	13
6	266	4
7	254	30
8	250	18
9	250	6
10	250	5
11	222	10
12	214	4
13	207	4
14	188	6
15	185	10

Table shows various levels at which sugar disappeared from the urine and did not reappear while these patients were under observation. The number of subsequent observations represent the number of blood sugar determinations that were made during the time these patients were being standardized with diet and insulin. At no time did sugar reappear in the urine.

These figures were taken during the transitional stage of diabetics while under treatment with diet and insulin. Many patients came in with higher blood sugars and had sugar in the urine. The figures quoted here represent the blood sugar level at which sugar disappeared from the urine and did not reappear in the subsequent daily observations that were made, even though the blood sugar concentration was on a steady decline under treatment with diet and insulin. There is perhaps some room for objection to this article because of this point, but my answer is this. Just as these patients had a rapid transitional stage from a high blood sugar to a lower or normal blood sugar level because the

failed because their diets were not accurately salt-free, and other specialists, have gone on record in writing that no patient can be induced to eat a salt-free diet for any length of time and that any results obtained are due to undernutrition. There is nothing impossible or abstruse about it, but anyone undertaking it must realize that the salt-free diet is more difficult than any ordinary diabetic or nephritic diet, and that it is not obtainable in most homes or in most hospitals without very special preparations and precautions. Also, patients who develop symptoms of salt privation on the very strict diet are few, but it is important that such symptoms be recognized immediately and treated by giving the necessary small allowance of salt.

Analyses of the blood and urine are indispensable, at first for the diagnosis and classification of the case, and later as a check upon the diet and progress. No one should attempt or claim to give a salt-free diet unless he controls it by at least an occasional chloride analysis of a twenty-four hour urine sample, for this is the only means of proving that the sodium chloride output is reduced to 0.5 gm per day. It is wrong to give haphazard general advice to avoid salt, with the idea that there is no harm in the trial and that stricter measures can be adopted later if the lax ones fail. Failure is the rule under such conditions, and a large proportion of patients then become skeptical or discouraged in regard to undergoing any more stringent application of the method. If a case of hypertension is complicated with nitrogen retention, diabetes, obesity or other disorder, there is nothing incompatible in the treatment of any or all of these combinations, but the diet requirements are somewhat more difficult for both the patient and the physician.

Several millions of patients cannot all be treated by a few specialists, and on the other hand most general practitioners are not very proficient in the management of diets. This practical problem is the same for both renal-vascular disease and diabetes, and a comparison with surgery may throw light on it. A surgeon can describe an appendix operation so that it appears even simpler than a diet treatment. Any of us could perform an appendectomy if necessary. Some physicians in isolated communities are compelled to cover

the entire field of medicine and surgery, and they do it well considering the conditions. Most of us who practice medicine do not perform major surgical operations, partly because we are too busy with other work, and partly because there would be a difference, even if it were as low as one or two per cent, between our operative mortality and that of an experienced surgeon. Also, major operations have been performed successfully in farmhouse kitchens, but a well equipped operating room is a better and safer place. Every diet specialist is affiliated with an institution with special equipment and a trained staff, and the very fact that he needs such an affiliation proves its importance for diagnosing, treating and teaching patients. A large proportion of physicians will be too busy to give the necessary attention to diet treatment, and will refuse to take on their consciences the responsibility for the poorer results which are yielded by half-way treatment in comparison with skilled treatment. On the other hand there is a great movement everywhere by some of the physicians, who are sufficiently interested, to train themselves to proficiency in the diet methods which are such an important new development in medicine, and a similarly extensive movement to establish metabolic clinics either independently or as departments in general hospitals, so as to provide the necessary place and equipment for accurate work. I am confident that the problem is being solved by the development of these numerous men and institutions at least partially specialized for metabolic treatment, and that general practitioners will either take pains to acquire the necessary knowledge and equipment or will refer their cases to others.

A closing exhortation is that physicians should realize the actual possibilities in the treatment of renal-vascular disease. Not long since, our profession was considerably scandalized by learning that Presidents of the United States do not necessarily receive the best possible medical care. A million or two of renal and vascular cases are still being treated by drugs and other antiquated methods, and a tremendous saving of disability, death and economic losses can be accomplished by extending to them the benefits of modern scientific management.

sionally be misled. We have all seen cases of so-called essential hypertension in which the systolic pressure ranged around 200 mm of mercury, but in which repeated kidney function tests failed to reveal any renal impairment. Conversely we occasionally see cases of advanced renal disease in which there is a low or normal blood pressure, especially where there is some cardiac involvement. One case referred to in this series had a negative urine and a blood pressure of 135/100, but the non-protein nitrogen content of his blood was 52 mg per 100 c c blood.

Coming back to the original question that if we cannot draw definite conclusions from the urine and the other renal tests have their limitations, how then should these cases be studied before operation if patients are to have the best that scientific medicine affords? I think the question is answered in careful blood chemistry determinations. Most modern hospitals have or have access to well equipped clinical laboratories, and of late years these blood chemistry procedures have been simplified. For practical purposes we need only to know the blood sugar concentration and either the non-protein or the urea nitrogen content of the blood. Three c c of blood is sufficient to make these determinations, providing the Folin Wu method is used. It is stated that six determinations can be made in about an hour and a half, so that the time element is not an especially important one. At the Albany Hospital a charge of one dollar is made for each individual determination, and this moderate fee does not put a prohibitive cost on blood chemistry as a routine procedure.

A fasting blood sugar concentration of 160 mg per 100 c c of blood, if not absolutely conclusive, is presumptive evidence that you are dealing with a diabetic, and if you get some of the higher levels that have been encountered, you will congratulate yourself that you knew of the condition before operation and can treat it accordingly. Likewise, when the non-protein nitrogen goes above 40 mg, or the urea nitrogen above 20 mg per 100 c c blood, you may rest assured that the patient has nitrogen retention and probably severe renal disease.

### CONCLUSIONS

1 Single negative A M specimens of urine are unreliable in ruling out the presence of nephritis or diabetes.

2 Twenty-four hour specimens are more reliable, but a negative twenty-four urine does not mean much.

3 Phenolsulphonephthalein tests are helpful if carefully done, but a high two-hour output will often give the surgeon a sense of false security, and a low output may cause anxiety where there need be no fear.

4 Blood pressure readings are of value but not conclusive.

5 The blood sugar concentration and either the non-protein or the urea nitrogen content of the fasting blood are the most conclusive single determinations that the surgeon can depend upon in ruling out the presence of nephritis or diabetes in preoperative cases.

## PRENATAL CARE

By JOHN O. POLAK, M.D.,

BROOKLYN, N. Y.

Abstract of the fourth clinical lecture in the course on Practical Pediatrics, given in the South Side Hospital, Bay Shore, April 1, 1925, under the auspices of the Suffolk County Medical Society.

The justification for the prenatal care of the pregnant woman is what it will do for both mother and child. We made a study of 3,000 cases of pregnancy and labor that were attended by senior students of the Long Island College Hospital Medical School. All of the toxemias and anomalies were sent into the Hospital. The first 1,000 had regular prenatal care by physicians at the clinic, and 19 babies were stillborn, and 6 died within two weeks after delivery.

The next 1,000 cases were seen regularly by visiting nurses who took their blood pressures and examined their urines and probably looked after them with greater detail than the average physician gives to his cases. In this group 47 babies were born dead.

The next 1,000 cases had no prenatal care, and in them 80 babies were born dead. The less prenatal care the mothers get, the higher the infant mortality among the babies.

In a demonstration of supervised midwives in Newark, there were 17 dead babies among 1,000 births.

Prenatal care will bring the death rate of newborn babies down to two and a half or three per cent.

What points are to be developed in prenatal care? The history is of great importance. Many have had one, two, or three babies born dead. Some were due to extra large babies, and some to contracted pelvis. One woman had had eleven consecutive breech deliveries of dead babies, and on this fact

deficiency of the pancreas was supplied in the form of insulin, so they had a gradual, perhaps very gradual transitional stage from normal carbohydrate metabolism to the severe diabetics that they were

At what point sugar appeared in the urine in this gradual upward blood sugar concentration is not known because these patients had passed their renal threshold when admitted and no diagnosis had been made until sugar appeared in the urine. When we as physicians and surgeons begin to make blood sugar determinations more frequently we will discover cases much earlier. This point is illustrated by the case of a rather obese railroad man who sought treatment for a scratch on his finger which for some reason did not heal up well. Two examinations of his urine were made at a three-day interval and both were negative. His blood was then examined and showed a blood sugar concentration of 280 mg per 100 cc of blood. This man had never used insulin, his diet had never been restricted, and he had obtained life insurance without difficulty, yet his subsequent stay in the hospital proved that his diabetes was very severe. These facts prove that it is possible to have a high blood sugar with a negative urine, and the surgeon who bases his conclusions on a single negative urine examination will occasionally be misled. However, the blood sugar concentration taken in the morning before breakfast is the most reliable single determination that can be made in establishing the presence or absence of diabetes.

#### POSSIBLE TO HAVE SEVERE NEPHRITIS WITHOUT ALBUMIN AND CASTS IN THE URINE

The idea of this paper was suggested to me by the case of a middle aged woman with carcinoma of the pylorus. The hospital admission specimen and the preoperative urine reports were negative. At operation it was found that this was a favorable case for pyloric resection, which was performed. This patient died within thirty-six hours following the operation, during which time she voided only about six ounces of urine, and this specimen was loaded with albumen and casts. Death was apparently due to a renal insufficiency. The point is this, that had the surgeon known that the patient had renal impairment, he would have been content with less radical measures at operation, and would not have increased his operative mortality by this case, but depending on the two negative urine reports he was misled. I have in mind another patient in whom the urine was persistently negative, but we were never able to get a total phenolsulphonaphthalein excretion above 25 per cent in two hours, and this on repeated examinations. There occurs to me now another patient whose urine was persistently negative, but his phthalein excretion was only 42 per cent in two hours, and the non protein nitrogen con-

tent of the blood was 55 mg per 100 cc of blood. Cases of this type are fairly common.

Another patient whose renal function was studied more thoroughly had two negative A.M. specimens of urine and one negative twenty-four hour specimen. Two phthalein tests were done, one of which was 23 per cent in two hours, and the other one 25 per cent in two hours. The non protein nitrogen content of the blood was 52 mg per 100 cc. The Mosenthal concentration test was also done and showed a specific gravity varying from 1012 to 1017. The two hour amounts ranged from 70 cc to 115 cc. The total day amount was 550 cc, and the total night amount 65 cc. This patient had three routine urine examinations which were negative, yet he had a definite renal impairment which was dangerous as far as an anesthetic was concerned, inasmuch as he was a surgical case.

These findings make one very skeptical about a single negative preoperative urine report and brings up the question of the advisability of more reliable preoperative renal and diabetic studies, especially where the circumstances of the case permit it and the patient is in the age group in which these complications are most often encountered.

#### LIMITATIONS OF THE VARIOUS RENAL TESTS

We are now facing the question that if definite conclusions can not be drawn from a single urine examination, how then shall we study these cases before operation?

Phenolsulphonaphthalein determinations alone are not always reliable and are only of value when carefully controlled and considered with other findings. Occasionally in a stout person a short needle is used and in such a case the dye does not reach the muscle, or when a larger needle is used, some of the dye runs out when the needle is withdrawn. The ampules contain more than one cc, consequently the patient often gets an overdose of the dye. Again we have all seen laboratory technicians who have some difficulty in matching colors. All of these things probably help to account for the conflicting reports we occasionally get from phthalein estimations. I recall one case which showed an excretion of 24 per cent in two hours and the next day the test was repeated by someone else and there was a sixty per cent excretion in two hours. It is hard to believe that the function of the kidney fluctuated to this extent in so short a time. Assuming that the above objections have been overcome we must admit that the phthalein test represents only the excretory capacity of the kidney for the moment and gives no true idea of retained products in the blood.

Blood pressure readings will be helpful in the nephritics, but if we base our conclusions on blood pressure and urine alone, we will occa-

measurement is that in which the doctor uses his thumb and middle finger to span the distance from the patient's wrist to her elbow. If he can span the distance, the arm is short and the pelvis is likely to be small.

Another point is the length of the middle finger. Normally it is much longer than the others. If it is nearly the same length as the others, and the ends of the fingers form a straight line instead of a pointed angle, an abnormal shape of the pelvis may be suspected.

The lumbo-sacral rhomboid or diamond, is easily observed, especially when the woman stands. The lateral points of the diamond are indicated by dimples which cover the posterior superior spines of the ilium. The upper angle is a dimple just below the third lumbar spine. The lower angle is the upper end of the furrow between the nates.

A line connecting the lateral points will cross over the sacro-lumbar joint, and a point just above the center of this line corresponds to the posterior landmark of the external conjugate.

Normally the angles of the diamond are equal. If the pelvis is flattened, the lateral measurement of the diamond is increased and the vertical is diminished. The result is not only a decrease in the antero-posterior diameter of the inlet of the pelvis, but also an increased prominence of the promontory which disturbs the inclination of the pelvic bone and still further lessens the pelvic inlet.

While examining the diamond, place a ruler along the spine touching the sacrum and the upper lumbar vertebrae. The forward curve of the back will leave a space between the ruler and the body. If the space is over 3 cm, lordosis and excessive tilting of the pelvis are present.

The poise of the body when the patient stands or walks has a suggestive diagnostic value. If a woman has a protruberant abdomen, she must bend the upper part of her body backward in order to balance the abdomen. The lordosis of the spinal column raises the pelvis posteriorly and lowers it anteriorly, and thus tilts it forward, and when the pelvis is tilted forward, the expulsive forces of labor are directed backward rather than downward.

When the pelvis is tilted, and labor pains begin, place the woman on her side with her thighs flexed strongly on her abdomen. This reduces the tilting and increases the size of the pelvis at least one centimeter, or enough to permit a head to engage. The position may determine whether a woman shall be delivered normally or instrumentally.

It is desirable that pregnant women wear corsets. They support the protruberant ab-

domen, and hold the baby in proper alignment for ready entry into the pelvis.

The fundus of the uterus rises three and one-half centimeters for each lunar month of pregnancy. Its average height at term is 35 cm, which, divided by 3.5, gives 10 lunar months, or the duration of the pregnancy.

The linea nigra, or black median line, reaches the height of the fundus. When the fundus falls at term, the black line is left higher than the fundus. This is a point of some value in determining the probable date of labor.

The distance between the anterior superior spines of the ilia is normally about two centimeters less than the distance between the crests of the ilia. This relation of size will be preserved if the pelvis is of normal shape, no matter what its size. But compressing the pelvis from before backward flares out the ilia and makes the inter-spinous distance equal to or greater than the inter-crestal.

The external measurement from the lumbo-sacral joint to the symphysis pubis is important. A measurement of 16.5 cm or less always indicates a flattened pelvis.

The position of the fetal heart may give important information regarding the progress of labor. It shows the descent of the body and its rotation, for as the presenting part descends, the heart comes nearer to the median line and descends toward the pubis. The important time to follow the fetal heart is while the baby's head is on the pelvic floor. During that period observation of the fetal heart will show the condition of the child. If the cord is short, or is compressed, or is twisted, the fetal heart, which normally beats 120-140 times per minute, will drop to 80 or less, but in the interval between pains it will gradually come back to its normal rate. If there is an obstruction in the pelvis, the fetal heart will become slower and slower. Also if the cord is tightened while the child is driven downward, a souffle will be heard with each beat. If the fetal heart is weakening, its beats will not go back to 120 between pains. A progressive slowing of the fetal heart is a sign of danger to the child.

A stethoscope may be worn attached to the forehead by head clips. This will enable the doctor to examine the fetal heart almost continuously while his hands are free.

If the uterine souffle is heard just over the symphysis before labor, a presumptive diagnosis of placenta previa may be made.

The physician can follow the progress of normal labor without making a vaginal examination. The position of the fetal heart indicates the descent and the rotation. A rectal examination shows the condition of the cervix and the position of the fetal head.

alone the doctor made a diagnosis of uterine fibroid, which caused the fetus to adjust itself as a breech position

The toxemias are often causes of the loss of babies at birth or soon afterward. There is a tendency for abortion to occur at an earlier and earlier stage. This is the opposite to the history of abortion in syphilis, in which the miscarriages occur at later and later stages until a living child is born.

Congenital syphilis is not so common in the pregnant as was generally supposed. From three and a half to six per cent is about the usual incidence in our hospital clinics.

Do not consider the uterus of a pregnant woman apart from the rest of the body. Every pregnant woman has the right to demand a full physical examination by her doctor. Her teeth, tonsils, heart, lungs, and thyroid are of special importance. The better care of teeth and tonsils in early life has lessened the incidence of heart disease as a factor in obstetrics.

Dr. Polak says he has not seen a case of eclampsia in a woman who has an enlarged thyroid. An enlargement of the thyroid is normal in pregnancy. In Spain it is the custom of mothers to measure the girth of the necks of their daughters after marriage to see if they are pregnant.

The kidney function is important in pregnancy, for the mother's kidneys have to bear the extra strain of excretion for the fetus. A woman who has had pyelitis or scarlet fever is likely to have a lessened kidney reserve.

There are four conditions to be especially considered in toxemias:

- 1 Blood pressure
- 2 The kidney function, especially the presence of albumin
- 3 The body weight
- 4 The thyroid gland

A reduced blood pressure is normal in pregnancy. The normal systolic pressure is from 95 to 110. If it goes to 125 and increases to 130 or 140, look out for trouble and examine the urine.

If the blood pressure is 110 or less, the urine is likely to be normal. Increased blood pressure antedates albuminuria by days and weeks.

A gain in weight of 20 pounds during pregnancy is normal. A gain of more than that is suggestive of edema and the retention of fluids in the body. Most of the gain develops during the second half of pregnancy.

What are some of the significant signs of trouble in pregnancy?

Headache is a late sign of toxemia. A frontal headache is characteristic. If prenatal care is given, the headaches will be prevented.

Changes in the retina are also late signs of toxemia. They will not develop unless there is a nephritic toxemia or a glomerular nephritis. Albumin, low specific gravity, and other

evident kidney signs will precede the eye signs.

Vaginal bleedings are significant. If they occur early in pregnancy, they suggest threatened abortion, or ectopic gestation or hydatiform moles. In the later months they suggest placenta previa, accidental hemorrhage, or premature labor.

Heart disease is no longer considered with the fear of former days. Think of the condition of the heart muscle rather than of the valvular lesion. A woman with damaged valves can go through labor safely if she is spared the efforts of straining. Suppose a heart case is in labor. She will go through the first stage without trouble if she is spared a nervous excitement from causes outside her body, by the employment of morphine and scopolamine.

In the second stage when the desire to strain is present, give an anesthetic, preferably ether.

In the third stage, when the uterus is contracted and an extra amount of blood is forced back into the circulation, permit some bleeding to take place from the venous side of her circulation in order to relieve the engorgement of the pulmonary circulation.

Use the functional test of the heart in order to determine the condition of the heart muscle. A standard test is to have the woman walk upstairs and down again, and note the pulse before, immediately after, and again three minutes after the effort. A return of the pulse rate to normal in three minutes indicates a good heart muscle.

How shall the breasts be prepared for nursing? The woman should wear a proper brassiere to support the breasts.

Previous to labor, wash the nipples daily with soap and water, and apply lanolin ointment. After labor, wash the nipples after each nursing and apply the following mixture: Boroglyceride, one part, and saturated solution of boric acid, seven parts.

Pelvic measurements have a great value in suggesting preparation for possible difficult delivery. If the pelvis is abnormally small, a baby's head can come through it if the head also is small. There were two slim little women who each had a small pelvis. One had two babies by normal deliveries, but the babies weighed only six pounds. The other woman had two babies by Caesarian section, but each baby weighed over eight pounds. The difference was in the babies rather than in the mothers.

There are two external signs which suggest the size of the pelvic outlet, 1, the length of the forearm, and 2, the shape of the lumbosacral rhomboid.

A short forearm goes with the general body build in which the pelvis is small. A rough

Legislative bodies, such as the county and state societies, and the American Medical Association, are doing organization work through delegated representatives from the county to the state and state to the nation, and while necessarily more conservative in thought, and slower in action than radicals and visionaries desire, are steadily progressing toward solid ground upon which the profession may securely stand in defense of our citizens from the attack of charlatany, and for their protection from the destruction of disease

The Medical Society of the State of New York, the largest medical group in the world, excepting of course the American Medical Association, located in the most populous community, and in the most fertile field for study, cultivation and development, is ever striving to give an increasing membership valuable return for their individual investment

The Journal, with a full time Executive Editor, is developing in its various departments, the individual interests of the membership On the scientific side, it prints the papers read before the State Society, the District Branches, County Societies, and other valuable contributions In the Legal Department it publishes most valuable and informative material based upon the discussion of actual cases selected from the great experience of our legal counsel

In the Legislative Department it elaborately prints matters of legislative interest, classified and indexed, and accompanied by lucid explanatory notes by our indefatigable Chairman of the Committee on Legislation, and by our executive officer In surveys of conditions affecting our members in counties and cities throughout the State, which are exhibiting conditions not previously appreciated, and spreading inspirationally valuable information The surveys have attracted wide attention and will be continued to cover not merely every county, but other general matters relating to public health whether conducted by scientific or lay organizations, with the hope that physicians may, through better understanding, become more interested and may be inspired to assume the leadership which should be theirs in all matters affecting the health of our citizens

The present Committee on Publication is studying, in detail, plans for the general improvement of the Journal, and will pass on to its successor many valuable suggestions Beginning in November, a distinguished Medical Editor will assume responsibility for a Department of Medicine and Surgery containing

brief abstracts of up-to-date scientific information written in a crisp, concise, easily read form

The executive officer, a full-time officer, created by the last House of Delegates, began his work last fall and has proven his value to the society in his legislative work at Albany in a convincing manner He has made as many contacts with individuals and with county societies as his time has permitted He will endeavor to discover the desires of the county societies and of their members He will try to interest non-member physicians and enlist them, and while at this moment our membership is numerically greater than it has ever been, we have a reasonable expectation that it will be considerably increased this year

Our Directory is of inestimable value to those who use it, but may be improved by the addition of new material

Defense in malpractice suits and the privilege of the special group rate for indemnity insurance are worth far more than the State dues The sober realization that the practice of medicine is a hazardous occupation, makes it beyond comprehension how any doctor can have a comfortable moment without both the assurance of defense and of financial protection

The activities of the Committee on Legislation have shown the way to the other committees of the State Society The money spent by this committee has been valuable to the profession at large, to the citizens of our State, and especially to members of the Society The conferences of the Legislative Chairmen have sent back interest and enthusiasm to every county society, have awakened warm inter-county relationships, and have been of greater value than any other activity

The committees on Public Health and Education and on Economics may be able, providing sufficient financial balances appear, to do similar work, holding annual conferences of committee chairmen and making these chairmanships important offices which will be held by men chosen because of their peculiar fitness

We often wonder whether many of our members appreciate the one officer of the county society who is usually the one who does more work and more thinking for the county society than all of the other officers combined We feel that the secretary is that man, and that annual meetings of secretaries, with seriously planned programs, should be held at the expense of the State Society, so that these officers, many of whom have satisfactorily held their places for many years, and who possess the greatest possible knowledge

The Medical Society of the State of New York is not responsible for views or statements, outside of its own authoritative actions published in the JOURNAL. Views expressed in the various departments of the JOURNAL represent the views of the writer.

## STATE SOCIETY ACTIVITIES

Thirty-five years of active medical service are cumulatively convincing to the writer of the value of social contacts with the members of our profession, and the value of mass relationships

By education rather than by any other se-  
What are some of the signs are placed in a  
trouble in - is more definite

perha omc

hundredth man in his community, he is regarded as qualifying his privileged place if he engages in extra professional activities. Tradition has honored him as respectable and poor, but looked askance at him, as having capitalized suffering, if he attains anything more than a modest financial success.

Sympathetic association with his fellows is as necessary to him as the breath of life. Self-preservation as a profession has compelled organizations, which, pyramided upon small local groups, up to and through state and national representation, have developed strong nation-wide groups which carry national re-

sponsibilities Every physician fails in his duty to his profession if he fails to assume his share of these burdens

Legislative bodies, such as the county and state societies, and the American Medical Association, are doing organization work through delegated representatives from the county to the state and state to the nation, and while necessarily more conservative in thought, and slower in action than radicals and visionaries desire, are steadily progressing toward solid ground upon which the profession may securely stand in defense of our citizens from the attack of charlatanry, and for their protection from the destruction of disease

The Medical Society of the State of New York, the largest medical group in the world, excepting of course the American Medical Association, located in the most populous community, and in the most fertile field for study, cultivation and development, is ever striving to give an increasing membership valuable return for their individual investment

The Journal, with a full time Executive Editor, is developing in its various departments, the individual interests of the membership On the scientific side, it prints the papers read before the State Society, the District Branches, County Societies, and other valuable contributions In the Legal Department it publishes most valuable and informative material based upon the discussion of actual cases selected from the great experience of our legal counsel

In the Legislative Department it elaborately prints matters of legislative interest, classified, and indexed, and accompanied by lucid explanatory notes by our indefatigable Chairman of the Committee on Legislation, and by our executive officer In surveys of conditions affecting our members in counties and cities throughout the State, which are exhibiting conditions not previously appreciated, and spreading inspirationally valuable information The surveys have attracted wide attention and will be continued to cover not merely every county, but other general matters relating to public health whether conducted by scientific or lay organizations, with the hope that physicians may, through better understanding, become more interested and may be inspired to assume the leadership which should be theirs in all matters affecting the health of our citizens

The present Committee on Publication is studying, in detail, plans for the general improvement of the Journal, and will pass on to its successor many valuable suggestions Beginning in November, a distinguished Medical Editor will assume responsibility for a Department of Medicine and Surgery containing

brief abstracts of up-to-date scientific information written in a crisp, concise, easily read form

The executive officer, a full-time officer, created by the last House of Delegates, began his work last fall and has proven his value to the society in his legislative work at Albany in a convincing manner He has made as many contacts with individuals and with county societies as his time has permitted He will endeavor to discover the desires of the county societies and of their members He will try to interest non-member physicians and enlist them, and while at this moment our membership is numerically greater than it has ever been, we have a reasonable expectation that it will be considerably increased this year

Our Directory is of inestimable value to those who use it, but may be improved by the addition of new material

Defense in malpractice suits and the privilege of the special group rate for indemnity insurance are worth far more than the State dues The sober realization that the practice of medicine is a hazardous occupation, makes it beyond comprehension how any doctor can have a comfortable moment without both the assurance of defense and of financial protection

The activities of the Committee on Legislation have shown the way to the other committees of the State Society The money spent by this committee has been valuable to the profession at large, to the citizens of our State, and especially to members of the Society The conferences of the Legislative Chairmen have sent back interest and enthusiasm to every county society, have wakened warm inter-county relationships, and have been of greater value than any other activity

The committees on Public Health and Education and on Economics may be able, providing sufficient financial balances appear, to do similar work, holding annual conferences of committee chairmen and making these chairmanships important offices which will be held by men chosen because of their peculiar fitness

We often wonder whether many of our members appreciate the one officer of the county society who is usually the one who does more work and more thinking for the county society than all of the other officers combined We feel that the secretary is that man, and that annual meetings of secretaries, with seriously planned programs, should be held at the expense of the State Society, so that these officers, many of whom have satisfactorily held their places for many years, and who possess the greatest possible knowledge

of local matters, should have opportunities to develop a close sympathy and to help to cement the county societies into harmonious understandings

While our information does not justify us in attempting discussion of a new budget, and will not until such a time as the collection of

the annual dues shall give us accurate knowledge of our finances, there is, however, every assurance that the members of the State Society are strongly behind, and willing to pay for real activities which have a reasonable degree of promise of success

N B V E

## THE YEAR'S PROGRESS

As the official year of the Medical Society of the State of New York draws to a close, and the officers and policies for the next year are about to be determined, it will be well to estimate the progress of the Society during the present year. We believe that the progress has been greater than in any previous year, and has kept pace with the evolution in other lines of scientific endeavor

The Society has had a wholesome growth with no retrogression in any line. The progress has been well balanced, with the strengthening of weak parts and the assumption of new activities. The Society is on the threshold of new opportunities, and is developing a mass consciousness and a pride of achievement. The name of Medical Society of the State of New York arouses respect and a feeling of pride in its membership and achievements. The people generally know that there is a State Medical Society and that it is doing things. Let us consider its achievements.

If the Society could answer the salutation "How are you?" Its reply would be "Fine!" There is an excellent morale throughout the ranks of the medical profession and a spirit of cooperation among the physicians. Medical Society meetings pass off with enthusiasm, their business is transacted with dispatch, new lines of endeavor are undertaken, and physicians generally plan their work in order to attend the meetings and find in them comradeship and an inspiration to give better medical service. The morale of the medical profession is convincingly shown by the deep interest taken by the leaders of the State and County Societies in the welfare of the organizations. They are willing and anxious to work for the Societies and for the welfare of the communities. The activities of the members have found its highest expression in the Committee on Legislation of the State Society, and the legislative committee of the County Societies. Literally hundreds of physicians now respond to calls for service where only dozens were active a few years ago. Cooperation has replaced individualism and collective action has replaced the zealous activities of the few.

Marked progress has been made morally. The practice of medicine was never on a higher plane and the influence of physicians in the community was never greater. Doctors

were a unit in demanding the repudiation of the legislative claims of quacks and cultists with no manner of compromise with them. The high ideals of the medical profession have been translated into action during the last year. The new spirit of progress is shown in a social way. Physicians call one another by their first names, and Society meetings are begun and ended with a luncheon or banquet. No one can fight a fellow practitioner whom he has met in a friendly way. The public is the gainer by this spirit of brotherhood.

One of the best yard sticks for measuring medical progress is the willingness of the members of the State Society to vote to double the annual dues in order that the activities of the Society might be developed to a greater extent and efficiency. The price does not deter physicians from getting what they want, and they want a better Medical Journal, more comprehensive legal protection, and a more available service of advice and assistance in conducting the affairs of the County Societies. All this costs money, and the increased demands which County Societies are making for expert help shows that the increase in dues is in accord with the spirit of increased service. The cordial reception given to the two full-time employees, the executive editor and the executive officer, demonstrates the approval of the increased dues.

The past year has witnessed new steps in the evolution of the practice of civic medicine. The medical profession has come to realize that it has a duty to direct the larger phases of disease prevention and the promotion of vigor among the people of a community. There are questions of educating the public, of building and managing hospitals, and of graduate medical education within the reach of all physicians. These are problems which can be settled only by medical organizations, and solving them constitutes the practice of civic medicine. One may confirm the recent progress in that line by perusing the pages of the Journal and noting the extension of the work into new fields and its adoption by an increasing number of county societies.

The progress of the past year is a prophecy of still greater results in the year to come. We are almost envious of the incoming president as new fields of opportunity open before him.

## OPPORTUNITIES

The fundamental duty of the Editor is to get information about the activities of the officers and committees of the State Society and of the new developments that have taken place in the District Branches and the county societies. This information is necessary in order that we may coordinate and correlate it for dissemination through the Journal.

An editor is also a teacher in that he is expected to formulate practical opinions and judgments. We have frequently been asked to give editorial comments on various phases of the activities of the officers and committees, because a question properly stated is already half solved. The editor is expected to express diagnoses and prognoses, and to write prescriptions for the benefit of the great mass of the members and for laymen as well.

We have always tried to acquaint ourselves with the formal actions taken by the House of Delegates, the Council, the Executive Committee, the standing committees, and the special committees, and to express ourselves strictly in accordance with the wishes of those in authority.

An examination of the editorial pages and the news columns of the Journal will show that we have confined ourselves to topics on which action has been taken by some official body in the State Society. Some of the records of these actions are hidden in obscure corners of the minutes or of official reports which have been approved.

We have kept our ears open to expressions of opinions from the members of county societies, and have tried to urge the assumption of practical activities by the county societies along lines which have been officially approved by the proper department of the State Society.

We desire to call attention to certain approved subjects which offer immediate opportunities for action and progress.

1 *District Branches*—It was the intention of the organizers of the Medical Society of the State of New York that the officers of the District Branches should function actively as advisors and leaders of the county societies. Great opportunities lie in the adoption of a definite plan of action to the end that the District Branches shall function throughout the year in close contact with the county societies.

2 *Periodic Health Examinations*—There are great opportunities in educating physicians to make periodic health examinations. The Kings County Medical Society has developed a practical plan of beginning the work by examining physicians themselves. New York County has formu-

lated statements regarding what an examining physician is to look for. There is an opportunity to extend these two lines of work to the county societies as a part of the educational scheme of the State Society.

3 *Graduate Education*—The greatest need of the medical profession is the education of physicians in the modern fundamentals of the art and science of the practice of medicine. There are great opportunities in the plan that the State Society shall assist the county medical societies to put on programs consisting of teaching clinics. The county societies have difficulty in securing first-class clinical teachers, but the teachers will gladly go when they are sent by the State Medical Society.

We have seen teaching clinics put on by county societies often enough to be assured of their success, and we have received a sufficient number of requests for such programs to convince us that the time is ripe for the State Society to undertake that activity. This is a great field of opportunity for the District Branches.

4 *Medical Publicity for Laymen*—The education of the people generally in regard to medicine has been frequently discussed in several departments of the State Society, and many different plans have been proposed, all of which come back to the fundamental basis of the composition of the articles. The range of subjects is enormous, and the difficulties of writing the articles are so very great that no physician has yet risen whose syndicated articles are eagerly sought by physicians generally.

We have conducted a Daily Press Department, and have subscribed to a clipping bureau for the special purpose of discovering a practical publicity idea which can be adopted by the State Medical Society. We believe that the best opportunity for publicity lies in the county societies and even smaller groups, as each seizes a local opportunity to write on a medical subject of which the people of the community are talking. It may be a scarlet fever outbreak, or a sewage disposal project. Wherever there is an audience and a topic for discussion, there let the local medical writer get busy. The opportunity lies in developing local talent for writing. Our Daily Press Department has often carried comments on especially good pieces of local medical writing.

We might continue our list of opportunities, but we will stop in order to give a practical illustration of a fundamental principle in all writing and speaking—not to present too many topics at one time, or at too great length.

## CLINICAL PROGRAMS FOR COUNTY MEDICAL SOCIETIES

We have frequently been invited to make suggestions regarding the programs of the County Medical Societies, and we have responded with the suggestion to make them clinical in character. The plan is that the local members shall bring a few cases, and the teacher or consultant shall talk about these particular cases and the medical principles that are involved in their diagnosis and treatment. Teaching clinics have been officially proposed by the Scientific Committee, and approved by the House of Delegates, and a committee has been appointed to study the problem. (See minutes of the House of Delegates as printed in the Journal in May, 1924, page 695.) A comprehensive plan of graduate education was developed and put in operation by the Medical Society of the County of Kings over two years ago, and in March of this year it was extended into Suffolk County, and

a series of weekly pediatric clinics was arranged and conducted along the exact lines approved by the House of Delegates, even that they should be aided by the State Department of Health. We made editorial comment on the plan on page 573 of our April 3rd issue, and on pages 658 and 659 of the April 17th issue. We described the Suffolk County Clinics on page 587 of the April 3rd issue, and we printed an abstract of the first lecture on page 653 of our April 17th issue. We are printing an abstract of the fourth lecture on page 735 of this issue.

The Suffolk County Pediatric course is an extension of clinical programs which had previously been carried out by the county society. We believe that any county medical society which puts on one or two clinical programs will wish to establish a graduate course in clinical teaching. F O

---

## A GENERAL SESSION

The reports of the officers and committees that will be given to the House of Delegates will touch upon many subjects which are worthy of a far more extended discussion than can be given to them during the meeting of the House of Delegates. Some of the reports concern the administration of the State Society, and are of little interest to the general run of members. Some reports are on questions of policy and the adoption of new lines of work which are of interest principally to the leaders and chairmen of committees. Other reports are on subjects in which every member of the Society is interested.

Some of the reports will be discussed at length, and others equally important will be passed by without comment. The greater part of the discussion will be over questions of the administrative policy of the State Society. There will be little discussion on any topic relating to social and scientific problems.

Many problems which are of deep interest to every member of the State Society will not be discussed simply because a place has not been made for them. There is need for an afternoon of general discussion when all the members may come together and discuss some of the newer problems which are barely touched upon in the reports of the officers and committees. We might suggest the following seven topics which would be of great interest to every member.

- 1 Periodic Health Examinations
- 2 Clinical Programs for County Society Meetings
- 3 The Practice of Civic Medicine by County Societies
- 4 Insurance Against Malpractice Suits
- 5 Medical Education of the People
- 6 The Nursing Problem
- 7 The Journal

We would make the presentation of these topics practical, and have the officers and chairmen tell what is actually being done in the State, and make definite suggestions for their adoption and extension.

There are now seven scientific sections, but not one of them covers this field of general topics, unless possibly the section on public health could do so. However, the object of the general meeting would be defeated if the topics were discussed in a section while six other sections were going on at the same time.

If we are a trifle enthusiastic in making this suggestion for a half day general meeting devoted to such general topics as we have named, the valid reason for our enthusiasm is that we are continually discussing them in the JOURNAL. We know that all doctors are thinking on these topics, and we would like to give abundant opportunity for their public discussion. F O

By GEORGE W. WHITESIDE, Esq.  
Counsel, Medical Society of the State of New York

## CLAIMED X-RAY BURN WITH RESULTANT ULCER AND AMPUTATION OF LEG

In this matter the complaint charged that the plaintiff had been referred to an X-ray specialist for the treatment of psoriasis. He claimed that on a certain day, in the application of the X-ray, the doctor was negligent and careless in that he exposed the plaintiff's body to an excessive amount of X-ray, for an excessive length of time, and placed the bulb or tube too close to the plaintiff's body, neglected to take proper care and the usual safeguards of filters and cones, and that by reason of this claimed negligence the skin and tissues of the plaintiff's leg were severely burned, injured and destroyed, and that he suffered an X-ray burn on his right leg which required extensive medical and surgical treatment and subsequent amputation of the leg.

The plaintiff, a man of about seventy-two years of age, had been afflicted with psoriasis for about fifty years, the disease affecting his elbows, his back and right leg. From time to time for many years he had received medical treatment for his ailment and was under the care of an able dermatologist who, after extensive treatment, suggested X-ray applications as a means of alleviating the affliction.

In the early spring he called upon the defendant for X-ray treatment. He was attended by a physician associated with the defendant who, during a period of four months, gave seven applications of X-ray to the right leg, the left elbow, and the lumbar region. These treatments were completed toward the latter part of June. The plaintiff did not return to the defendant's office until the end of the following October, at which time the defendant treated the right leg and right elbow with X-ray. Another treatment was given to the right leg and right elbow about three weeks later. The factors of dosage used in the October and November treatments were

Time	Distance	Gap	M-a	Filter
Oct 5th	11	9	45	1
Nov 4th	8	7	5	1

The October dosage is about sixty-five per cent of an erythema dose and the November dosage about sixty-four per cent. At both of these times the psoriasis upon the elbow being generally diffused, no lead sheet was used upon the elbow. The psoriasis upon the right leg being in a concentrated spot, in the application of the ray to the leg a lead protector was placed on the leg over the area adjoining the psoriasis and not to be radiated.

On the day following the last application the plaintiff returned to the office of the defendant and stated that during the night the spot on the leg became irritated and red. The defendant gave the plaintiff a wet dressing containing zinc oxide, carbolic acid, glycerine and lime water in the proper proportions and advised him that within a few days the redness would disappear. Nothing further was heard from the plaintiff until the institution of this action, except that about fourteen months after the last treatment the plaintiff wrote the defendant claiming that at the last treatment the defendant had burned him in the application of the X-ray.

When this action came on for trial the plaintiff testified that at the last X-ray application given by the defendant the glow from the tube was stronger than on the previous applications, so that it was necessary for him to shade his eyes with his hand and that when the ray was applied to the leg he felt a sensation of air currents, which he claimed he had not felt when the ray was applied to his elbow at that treatment or on any of the previous treatments. He further testified that he had received no medical care or attention for his leg until the following August, a period of about eight months after the X-ray application by which he claimed he was burned, that in the following August, while in the mountains on his vacation and during the night, his leg suddenly became very painful and the skin broke open and that the under-flesh was black, that he received medical attention from his physician at the hotel and then returned to his home, and that from that time until a year from the following November, he was under constant medical care for his leg, that the ulcer which had formed on his leg continued to grow larger, that at one time a curettage was performed and that gangrene developed and that it subsequently became necessary to amputate his leg. He also testified that the application of X-ray to his leg was at a point about five inches below the knee. A photograph of his leg introduced in evidence, which was taken on the day preceding the amputation of the leg, disclosed the ulcer in the lower third. Under cross-examination of the plaintiff (which facts became known to the defendant only a few days prior to the trial), it was developed that in January, March, April and May following the treatment in November by the defendant, the plaintiff had received X-ray treatment from

another physician. He admitted that the dates, factors of dosage, amounts paid, and parts of the body radiated by the other physician were correct, except that he denied that the other physician treated the right leg, but claimed that the other physician treated the left leg. On behalf of the defendant it was proved that the amputation of the plaintiff's leg was due to the disease of endarteritis obliterans or thrombo angutis obliterans and that the ulcer was the result of this disease and not caused by any overdose of X-ray given by the defendant. It was also proved that the redness of which the plaintiff complained was the static or electrical reaction and that it would disappear within a few days with no untoward results. The plaintiff called as an expert in his behalf a physician who had been practicing for over forty years and who, on his direct examination, testified that he was familiar with X-ray reactions or so-called X-ray burns and with the disease of endarteritis obliterans and ulcers resulting from such disease. On cross-examination, however, it was shown that this particular physician could not with any definiteness state when or where he had treated an X-ray burn or the disease of endarteritis obliterans—whether he had done so within the last five years or within the last ten years. It was also brought out on cross-examination that

he had never seen the plaintiff until about a month prior to the trial and that he was being paid for testifying as an expert. On behalf of the defendant it was proved by various physicians, as witnesses, that the factors of dosage used by him were proper and would not cause an X-ray reaction or burn, that the redness complained of by the plaintiff was the static or electrical reaction which is quite frequently seen in X-ray applications, particularly where a lead covering is used to protect the parts adjacent to that to be radiated. It was proved by a surgeon who examined the plaintiff a few days prior to the amputation that the ulcer was not one due to an X-ray burn, but due to the disease of endarteritis obliterans, which fact was also proved by the surgeon who performed the amputation. By a physician who had made an extensive study of the disease of thrombo angutis obliterans it was proved that this is a progressive disease and that an ulcer may be caused at any time by the slightest trauma, or may result without any trauma, and there is no known cure for the disease except amputation.

Upon all of this evidence the case was submitted by the trial court to the jury, which did not take long in their deliberation, and returned a verdict in favor of the defendant, dismissing the complaint.

### NEEDLE BREAKING IN HYPODERMOCLYSIS

In this action the defendant, a surgeon who had operated upon the plaintiff, was charged with the negligent breaking of a needle and the failure to notify the plaintiff of the fact and permitting the broken needle to remain within the plaintiff's body for a period of time.

The defendant operated upon the plaintiff for the removal of a fibroid tumor, which operation was carefully and skilfully done in accordance with the most approved technic. Upon the completion of the operation, the patient was returned to her bed and instructions given by the operating surgeon to the house physician to administer to the plaintiff a hypodermoclysis of a saline solution about two hours after the completion of the operation. The hypodermoclysis was prepared by one of the hospital nurses and the needles inserted by the house physician underneath the patient's breasts. Upon the completion of the administration, in withdrawing the needles the shaft of one became dislodged from the hilt and remained within the patient's body.

The defendant was not present at the time of the administration of the hypodermoclysis and upon the breaking of the needle was notified by the house surgeon of this fact. He thereupon visited the patient and probed for the needle, but

was unable to locate and remove same. The patient at this time was not informed of the breaking of the needle. At a subsequent time, when visiting the patient, the surgeon made a small incision over the site where the needle had entered the body and endeavored to extract the same, but again was unsuccessful in procuring the broken needle. The surgeon had to stop his attempts because of the protests and highly nervous condition of the patient. The patient remained in the hospital only the normal period of time after the operation and visited the defendant at his office for post-operative treatment. At one visit the patient complained of a pricking sensation at the top of the breast. At this time the surgeon made a small incision at that point and with forceps extracted the broken needle, which he unthinkingly laid upon his desk and which the plaintiff took possession of. The presence of the needle did not cause the plaintiff any particular injury or inconvenience.

After the case had remained upon the calendar for several years and the plaintiff's attempts to procure a settlement were unsuccessful, the action was finally abandoned and the complaint dismissed, terminating the action in favor of the surgeon.

# State Department of Health

## DISTRICT STATE HEALTH OFFICER BITTEN BY RABID DOG

Doctor Richard Slee, District State Health Officer for Nassau, Suffolk and Westchester Counties was bitten on the hand recently by his pet dog which was ill at the time but not with symptoms pathognomonic of rabies. A few days later the dog was killed and pathological examination of the brain showed that it was suffering with rabies. Dr. Slee is now taking Pasteur treatment.

In Westchester County a 4-year-old child died of rabies on April 15th, having been bitten on March 26th by a dog proven to have had rabies at the time. The State Department of Farms and Markets has had reports of several cases of dog rabies in Southern Westchester County, and has established a quarantine for dogs in that area.

In view of this unquestionable prevalence of dog rabies it will not be amiss to call attention

to certain procedures which should be carried out in all instances of dog bite.

1 All cases of dog bites should be reported to the health officer (this is *required* by the Sanitary Code if there is suspicion that the dog is rabid). The health officer will take charge of the dog, confining him for such time as is necessary to determine if the dog has rabies, or if the dog is killed he will have the necessary laboratory examinations made to determine whether the dog was rabid.

2 All dog bites should be thoroughly cauterized at once with *fume nitric acid*. This is the only cauterizing agent of value in the prevention of rabies, but is not effective unless used within 24 hours after the bite.

3 If the dog was rabid, commence Pasteur treatment at once.

## THESE DEATHS FROM DIPHTHERIA MIGHT HAVE BEEN PREVENTED!

During the week ending April 18, the Division of Communicable Diseases received supplementary reports on the deaths from diphtheria of nine children.

With one possible exception, the circumstances involved were such that a greater degree of care might have prevented death. In at least seven cases the patients were not seen by a physician until later than the first day of the disease. In the two remaining cases the reports indicate that a physician saw the patients on the first day. In one of these, however, the doctor apparently did not recognize the disease, as no antitoxin was given until the child was taken to a hospital four days later. In the other case which came to the attention of a physician on the first day of the disease, the child died a few hours later, autopsy showing respiratory obstruction at the bifurcation of the trachea, so that the intubation performed five hours previously had been of no avail. Unfortunately antitoxin was not given, as the diagnosis was not made until a positive culture was obtained after death.

One child "was getting along well, when he

got up to go to the toilet, he toppled over and died in a short time." This death occurred on the twelfth day of the disease, no antitoxin having been given until the fifth day. This is a common history and not only illustrates the need of early administration of antitoxin, but also indicates that greater care should be taken to keep patients in bed during convalescence.

*None of these nine children received antitoxin earlier than the fourth day of the disease.* In seven cases the parents were evidently remiss in failing to summon a physician at once. In only one case, however, was antitoxin given on the day of the first visit of a physician, although nearly all were seen so late that the patients might well have been given the benefit of any doubt as to the diagnosis. In two cases at least the physician apparently waited for the result of a culture before giving antitoxin, although the culture was not taken until late in the disease.

*If diphtheria is suspected, antitoxin should be given immediately.* The proper use of the culture is to determine the period of isolation and to confirm, not to make a diagnosis.

## VENEREAL DISEASE CLINIC ACTIVITIES INCREASE

The number of indigent patients treated at the forty-five venereal disease clinics in the State last year was the largest since the clinics were established five years ago. Four thousand seven hundred and forty-three new cases of venereal diseases were admitted for treatment, 2,789 cases

continued treatment from the year before and 3,594 patients who had discontinued treatment were persuaded to return for continuance of treatment. This total of 11,125 indigent cases of venereal diseases were given 120,383 treatments.

## DIPHThERIA NOT RECOGNIZED—CHILD DIES

A report has been submitted to the Department on the death from diphtheria last January of a child six years of age. According to this report, the child was taken ill on January 2, but was not seen by a physician until January 6. It is stated that the roads at this time were almost impassable. The physician made a diagnosis of tonsilitis and gave no antitoxin. Apparently he took no culture. When he was called a week later, the child

was dying. At this time he gave 12,000 units of antitoxin intramuscularly, which was, of course, too late to be of any value.

This is one of the many cases which have come to the attention of the Department where, evidently, it would have been better for the physician to take the risk of erring on the side of safety by giving antitoxin. If this had been done here, the child's life might have been saved.

## FAILURE TO DIAGNOSE DIPHThERIA

Early in November a practitioner was called to attend a child of about five years of age. He made a general examination of the child, also taking the temperature and pulse and prescribed the necessary medication for the condition. He was not called again until the latter part of November, at which time he examined the child with a stethoscope, also examining the throat and taking both the temperature and the pulse, and after examination made a diagnosis of croup. Upon his examination of the throat he saw no evidence of membrane. The necessary medication was prescribed and instructions were given as to the child's diet. The doctor also advised the mother to use a croup kettle, to

keep the child's bowels open with milk or magnesia, that the child was to remain in bed, and that he would call on the following morning.

On the following morning, the child not having responded to the treatment of the previous day, the doctor advised the removal of the child to the hospital, as there was impairment of breathing, and it would probably be necessary to intubate the child. The child was removed to the Willard Parker Hospital, where it was intubated. Two days thereafter the intubation tube was removed, upon which day the child died the cause of death being given by the hospital as diphtheria and bronchial pneumonia.

## DIPHThERIA DEATHS STIMULATE PREVENTIVE WORK

According to a recent report of District State Health Officer Sears, five cases of diphtheria have been reported in the city of Cortland during the present year. Three of the patients died. Dr. Sears hopes that in view of this experience the work of immunization against diphtheria will now be pushed vigorously in this city.

In the same report, Dr. Sears makes mention of the results of the diphtheria immunization campaign in the village of Solvay. Formerly diphtheria was prevalent almost continuously there, but following an intensive toxin-antitoxin campaign there has not been a case reported in that village since last October.
